The AUTHOR's

P R E F A C E

T O T H E

R E A D E R,

Containing a SYNOPSIS of his Method.

I.

THAT the Reader may the better apprehend our design and aim, we have thought fit to premise some things concerning the Methods, both general and particular, we make use of in the following Treatise. For as heretofore a sort of a blind deference to, and superstitious Veneration of Antiquity, and especially of Aristotle, has hindred the growth and progress of Natural Philosophy, which of late has made such considerable advances, since it has ventured to stand upon its own Bottom, to make new Additions to former Inventions, to essay new and unknown Objects, to substitute Things instead of Names, Certainties instead of Doubts, and Experience in the room of dull Credulities; not derogating in the mean while from the deserved Praises of the Ingenious among the Ancients: So without doubt Mathematicks also, unless our Predecessors had imagined that it had long ago been brought to its utmost Perfection by Euclid, Archimedes, Apollonius, and other Ingenious Ancients, would have arriv'd long since to a higher pitch, and by this time have surpass'd those Limits, which now we admire its arrival to.

Preface to the Reader.

II.

It is confess'd by all, that no Human Knowledge whatsoever can lay a more just claim to an unshaken Evidence and Certainty, or boast an higher necessity of its Demonstrations, or a greater multitude of undeniable Truths, than the Mathematicks ; and that those Propositions we have, found out by Archimedes, demonstrated by Euclid, Apollonius, and others, are at the same time unquestionable and altogether wonderful. But we may with Truth affirm, that most of their Propositions may either be disposed in a better order, or propounded easier, or demonstrated more evidently and directly, or taught after a more short and compendious way, now at least after they are already found out, and with a great deal of Pains demonstrated by their first Inventors ; and of this Opinion are several of the best and most celebrated Mathematicians of the present Age.

III.

It is certain Euclid has demonstrated several Propositions, (as Prop. 2, 3, 20, 30, lib. 1. 2, 5, 6, 10, 15, 28, 29, lib. 3. &c.) whose Truth to any attentive Person appears from the very terms, more clearly and certainly than the truth of Axiom 13. lib. 1. which his Interpreters dare not admit without a Demonstration. And tho' those superfluous Demonstrations derogate nothing from the certitude of the thing, yet by an unnecessary increase of the number of Propositions, and (which frequently follows thence) an inverting the order of things, they breed Tedioufness and Confusion.

IV.

There are none, unless those who are bigotted to Antiquity, but must own that the Elements of Euclid are destitute of a just and orderly Disposition of things. For to omit, that in the first Book there are ~~bundled~~ several sorts of Subjects, and a great variety of Properties demonstrated of them promiscuously without any respect to similitude or conveniency ; there is this never to be excused,

Preface to the Reader.

excused, that, after he has in the first Book deduced and demonstrated some particular Affections of Magnitude, he proceeds, in the second, to those things which are universal and common to any quantity; then in the third and fourth, he contemplates the Circle and the Properties of Figures inscrib'd in it, or circumscribed about it; in the fifth again he treats of the universal Doctrine of Reasons and Proportions; and yet not so universally, but in the seventh again he is obliged to demonstrate the same of Numbers particularly, which might have been done for all Quantities whatsoever, by one general Demonstration.

V.

Then as for the method of Demonstrating used by the Ancients; it is true that it nicely regarded the certainty of its Conclusions, nor would it admit any thing into its Demonstrations, which was not either a first Principle and so self evident, (called by them an Axiom) or might not be supposed, beyond all Contradiction, possible to be effected (and on that account named a Postulate) or, thirdly, an arbitrary Denomination of the thing proposed which needed no Demonstration, (and was called a Definition or Explication of a Term;) or, lastly, which had not been evidently demonstrated before: Yet I believe none will deny, but that this Method would have been more deservedly esteem'd, if with the certainty of its Conclusions it had joined a greater Easiness, Brevity, and Evidence, which is wanting in most of the Demonstrations of the Ancients; who thought it enough, firmly and infallibly to establish the truth of their Theorems, and extort the Assent of their Readers; little regarding by what Ambages, by how many circumambulatory Propositions, and almost whole Volumes, it was done; that thereby they might be forced to acknowledge the thing to be so, while how it came to be so, or from what intrinsic Cause or Condition of the Subject requiring it, such and such an Attribute agreed to it, remained in the mean while obscure, or altogether unknown.

Preface to the Reader.

VI.

Hence they made such frequent use of Apagogical Demonstrations, or deductive ad absurdum & impossibile, which ought not to be done, but where no ostensive Demonstration can be had, or for illustrating negative Propositions rather than demonstrating them; for the method of Deduction ad impossibile, does not so much demonstrate the Truth it self directly, as the consequent Absurdity of the opposite Supposition; whence it follows very indirectly, (tho' most certainly) that the Proposition is true, while in the mean time the original Reason of its Truth remains altogether hid and in the dark.

VII.

But that we may not seem unjustly to reject the particular Method of the Ancients, made use of by Euclid, as in lib. 12. Prop. 2, 10. &c. and by others, but especially by Archimedes, who peculiarly addicted himself to it, whence it has been by some called the Archimedean Method, and by Renaldinus the Method per Explosum excessum atque defectum; besides its Deduction doubly ad absurdum, whereon it always relies, as e. g. it infers the equality of two Magnitudes A and B by a far fetch round-about way, by shewing, that if B be supposed greater or less than A, from either Position there would follow an absurdity; and thence as it were begging the Equality by a new Inference, which tho' it may pass free from Suspicion, yet it neither ought, nor can be admitted, without this Limitation: In comparing those things whose Natures are capable of Equality, if it can be demonstrated that the one is neither greater nor less than the other, we may thence justly infer their Equality.

VIII.

The Learned are now generally agreed, that, besides that Synthetick Method, whereby the Ancients either ostensively deduced their Problems and Theorems from evident and common Principles,

Preface to the Reader.

ples, or apagogically demonstrated them by Deductions ad absurdum, they also made use of a certain sort of Analysis, whereby they found out those Theorems and Problems; and which, to raise the greater Admiration in their Readers, they afterwards studiously conceal'd and kept to themselves: Which Method is undoubtedly preferable to the other, as not only demonstrating the certainty of the Propositions so found, but at the same time shewing the invention of them too; and this is that Method that Vieta, Harriot, and Des Cartes, and their Followers have not only brought to light in this last Age, but to a great degree of Perfection too, and whereof Carolus Renaldinus, in that vast Work he has intituled *Ars Analytica Mathematicum*, has given us a large Treatise.

IX.

There has appear'd moreover of late another particular Method * invented by Bonaventura Cavallerius, which is called the Method of indivisibles, whereby the most difficult and abstruse Problems of Geometry are found out and Demonstrated with an incredible ease, which is the above-mentioned Renaldinus's Opinion of it, lib. i. Resol. & Comp. p. 239. which, to demonstrate the Equality or Proportions of Figures and Bodies that may be compared with one another, goes to work after a way which seems to be more natural than any other, by supposing plane Figures to consist of innumerable lines, and Solids of innumerable Plans (called their indivisible Parts or Elements, because the Lines are conceived without latitude, and the Plans without any thickness,) and relying on this self-evident Axiom, That if all the Indivisibles of one Magnitude collectively taken, be equal or proportional to all the correspondent indivisibles of another, or taken separately each to each, then also those Magnitudes will be equal or proportional among themselves. Which Inference can be guilty of no Fallacy, nor liable to any Error, as long as those Elements are taken and conceived in that sense their Authors design them; which is sufficiently demonstrated by Renaldinus, lib. i. Compof. & Resol. p. 245. towards the bot-

* Dr. Wallis is of Opinion this is nothing but an Improvement of the Ancients Method of Exhaustions.

Preface to the Reader.

from, and at the beginning of p. 306. and also by Honoratus Faber, in his Synopsis, p. 24. and Dr. Barrow in Lect. Geom. p. 24. and the following, against Tacquet and the other Adversaries of this method.

X.

There is another Method a-kin to this, which may be properly named Generative, very much followed by Faber in his Synopsis, and Barrow in his Lect. Geom. whose Author Renaldinus tells us was Guldinus, lib. Cit. p. 253. shewing at large its Rules and Foundations in the following pages, viz. The rise of Lines from certain motions of points; of Plane and Curvilinear Surfaces, from the determinate progress or rotation of a given Line, and of Solids by the various motions of various Surfaces; the Productions whereof are so represented to the Imagination, that the intrinsic nature of the magnitudes thence arising may become known, and their Properties and Affections may, from their Natures thus known, be easily and briefly deduced.

XI.

Near a-kin to this Method of Cavallerius is that other of Infinite Progressions, wherein having found a certain Progression of like Parts circumscrib'd about, or inscrib'd in any given magnitude, which may be continued by Bisection ad infinitum; and then at length (by virtue of the Doctrine of Exhaustions, founded on Prop. 1. lib. 10. Eucl.) will terminate in the magnitude it self, I say, wherein the sum of those infinite Terms, collected by Rules on purpose for the addition of those Progressions, and consequently the quantity or proportion of the proposed Magnitude, to any other given one, may be expressed or defined. But this termination of Figures infinitely circumscribed or inscribed in a Circle, not pleasing Renaldinus (altho' his Dissention seems only to consist in Words,) he exhibits another Method like it, (which he peculiarly calls his own) built on twelve fundamental Theorems, and illustrated by several Examples, lib. 1. de Retol. & Comp. p. 277 & seqq.

Preface to the Reader.

XII.

Of late also, the most ingenious Mr. Isaac Newton, to demonstrate his *Philosophiæ Naturalis Principia Mathematica*, lib. 1. sect. 1. premises some Lemma's of his method of Rationes primæ & ultimæ, or evanescent quantities, thereby to avoid the tediousness of deducing long and perplexed apagogical Demonstrations after the way of the Ancients. For finding that his Demonstrations might be very much contracted by the method of Indivisibles, and knowing at the same time, that that method was scrupled by some, and thought not very Geometrical, he rather chose to found his Method on the sums and proportions of quantities which he calls Evanescent, which performs the same as the Method of Indivisibles, and may be more safely used; which he inculcates in these very words, and others such like, in Schol. of Lemma. 11. And also answers several objections which might seem to make against it.

XIII.

But it would be in vain for us to attempt, in this place, to explain all and each of those various methods at length; having only proposed to our selves, to demonstrate the chief and principal Theorems and Inventions of the Mathematicks, and to use sometimes one of them, and sometimes another, (having first Demonstrated their Foundations) according as we shall judge this or that of them, fittest to Demonstrate the thing in hand, and so shew the reasons, and use of each of them in the process of this discourse. And altho' H. Faber in his Synopsis, p. 8. Insinuates, that Analytick terms ought not to be made use of in Geometrical Demonstrations, because that Algebraick method seems to be too difficult for young beginners; yet we are of the quite contrary opinion (nay we can scarce doubt but that that Ingenious man would also agree with us herein, if he saw the way we make use of those foundations of Algebra, which is only of the most simple and general principles of it) especially in this case, where the said method is by little and little instill'd with the Demonstrations themselves; and the literal Computations taught from their first
Princi-

Preface to the Reader.

Principles, than which nothing is more easie: And this is that which we design to do, and so use the learner by degrees to this sort of Demonstration, thereby to prepare him the better for the Analytick Geometry of the Moderns, which is the highest apex of the Mathematicks. But we had rather our Reader should himself find, than we trouble our selves any further to tell him here, how compendiously we Demonstrate the Propositions of Geometry, by the help of these Analytick notes, without the tedious Concatenation of a long Chain of Consequences, which would be otherwise unavoidable.

XIV.

After this way we design to go through the following Scheme.

1. *We shall deduce several propositions of Euclid, Archimedes, and Apollonius from our definitions, and the generations of Magnitudes therein proposed; as Corollaries necessarily flowing from them, and confirm'd only by an immediate and simple consequence.* 2. *We shall demonstrate their chief Theorems (for the sake of which they were forced to Demonstrate several others before-hand, the knowledge whereof for their own sake was not so necessary or valuable) without any long series of antecedent Propositions, or Foreign principles, from a few direct and intrinsic Principles of their own.* Whence 3. *It will follow, that after this Method we shall propose things, and treat of them, in a more natural Order, and first of all deliver those which are most universal and common to all quantities, and then descend to those which in a more special manner regard Magnitude; and distribute and dispose all according to certain general distinct Classes of the things to be treated of, and their affections.* Hence also 4. *We deduce from those universal Theorems, by way of Corollary, the Precepts of vulgar Arithmetick, and specious Computation, which afterwards we make use of in particular Demonstrations after a very short and compendious way; and, for this very reason, some Learned men of the present Age are of opinion, that the Ancients often fell into that tedious and intricate prolixity in their Demonstrations, because they would not acknowledge the great affinity there was between Arithme-*
tick

Preface to the Reader.

tick and Geometry, taking particular care not to introduce the Terms and Operations of Arithmetick into Geometry; tho' at the same time they never scrupled to transfer the names of Plan, Square, Cube, and such like to numbers. 5. Lastly, Having first Demonstrated the first and Fundamental Theorems of Elementary Geometry, we may safely build on them the Praxes of all kinds of Mathematical Arts, that are most useful and requisite to several Exigencies of human Life, as, first, Trigonometry both Plain and Spherical, the Construction and use of the Tables of Sines and Tangents. 2. The Construction of Logarithms, and a compendious application of them to Trigonometry: and in the 3. and last place, the fundamental Precepts of Algebra, or the Analytic Art; by the help whereof the learner may at length arrive to the higher and more reclude parts of Geometry, and become master thereof: Not to mention several Geometrical and Arithmetical Problems, which we have all along derived from several of our Theorems, by way of Corollary, which it may be some other time, may make an Appendix of this work.

XV.

And thus when we shall have Demonstrated not only the chief Theorems of the Ancient Mathematicians, omitting the unnecessary crowd of those that are only Subsidiary, but also have demonstratively deduc'd the fundamental Precepts of the most necessary and useful Arts that flow from them, and that are abstracted from matter, as of Arithmetick, Trigonometry, and Algebra; I hope none will doubt but that in this little Volum we have exhibited, as it were the Nucleus or Kernel of the pure and genuine Mathematicks (for those other Sciences and Arts which go by the name of mixt Mathematick, are most of them parts of natural Philosophy, from the application of Mathematicks to the Phenomena of nature) and so may justly bear the name of Mathesis Enucleata.

XVI. N^r

Preface to the Reader.

XVI.

Nor are we ignorant, nor shall we conceal what several Learned men have both proposed and already done, for removing those difficulties and blemishes of the Ancient Mathematical Methods we have just now mentioned. The late Admonishments of the anonymous Authour of *L'Art de Penſer*, no leſs ingeniously than modestly delivered, Part. 4. Chap. 9. 10. of the ſaid Treatiſe, are ſufficiently known; as alſo the laudable endeavours of A. Tacquet and Honoratus Faber and ſeveral others above mentioned for contracting, new ordering, and more eaſily and directly Demonſtrating the chief Geometrical Inventions of the Ancients. There are moreover extant of a certain anonymous Author, *Elementa Geometrica novo ordine ac methodo ferè Demonſtrata*, Printed at London about 26. Years ago. There are alſo F. Ignatius Gaſton Pardies *Elemens de La Geometrie, &c.* Translated into Latin after the third Edition, by the Famous Schmidtiſius Profeſſor at Geneva: As alſo of F. Mich. Mourgues's, of the Society of J. Nouveaux *Elemens de Geometrie*, abreges par des Methodes particulieres en moins de Cinquante propoſitions, &c. There are alſo ſeveral other Eſſays of reducing the Mathematicks into a better Order and Method, the titles whereof we have only as yet ſeen; and even while theſe papers were in the Preſs, there happen'd into our hands a Treatiſe of F. Lamy's Entituled *Les Elemens de Geometrie, ou de la meſure des Corps, &c.* Printed at Paris in 1685: ſo that we may only ſeem to ſome to do what has been done already, in endeavouring to ſhew our Reader a new and ſhorter way to the Mathematicks.

XVII.

But as none can blame Jacobus le Maire, becauſe, after the happy diſcovery of the Magellanick Paſſage from the Atlantick into the Pacifick Sea, he would needs yet endeavour to find another ſhorter, which he accordingly did; nor can they be blamed, who now a days conſult about finding one from theſe parts of
the

Preface to the Reader.

the World, by the North to the East India's. Thus also, in an affair of that moment, that one or a few are not sufficient to bring it to Perfection, if any one who comes after, not only invited, but also assisted by the ingenious Endeavours of those who have gone before him, shall undertake to add to their Inventions, to help on the business by his advices, and shew what things are capable of a further Polish, and the method how to perform it, doubtless such an one ought not to be blamed, nor accused of arrogance, unless at the same time he endeavours to deprectate the essays of others, and cry up his own as the only valuable; Which how far it is from our design, the work it self will abundantly shew. Moreover as the senses of men are differently affected by different Objects, and their Palates have different Relishes of the same thing, according to different Preparations of them: So the same truth takes and insinuates it self more easily with one proposed and demonstrated after this way, more with another after that way; and we are so much the more likely to suit the different genii of different Persons, by how many more and different methods and ways we shew them, leading to the same end, of which every one may take that which he likes best.

XVII.

We therefore Publish, by the Divine assistance, these our Endeavours also, after so many other ingenious and elaborate ones in the same kind; nor can we doubt the approbation of some of our Readers. This at least we can experimentally affirm: That not a few of those to whom these our thoughts were partly publicly read in Lectures, and partly privately taught (for they were only design'd for Learners) were not a little taken with the Concise brevity and facility of the Demonstrations; so that we may reasonably hope to be acceptable to those, to whom either time, or sufficient force of genius is wanting, to run over the vast Volumes of the Ancient Mathematicians, and comprehend their prolix Demonstrations, and long series's of far fetch'd Consequences; and as for those who have both leisure and genius to do so, this may serve for an Encouragement towards it; that after they have gone through the chief truths and propositions

Preface to the Reader.

sitions they contain, Demonstrated in a more ease and shorter way, they may so much the more confidently adventure upon those celebrated and ingenious Treatises, from the reading whereof they were before deterr'd by the length and almost insuperable difficulty of their tedious and perplex Demonstrations.

XIX.

Being now about to enter upon the matter it self, we will only further hint these few things. 1. Since our whole design is for the advantage of young Students (which ought to be a Professors chief Care and Study) we must not omit the Explication of the most simple terms; especially since we design to deduce some Corollaries immediately from them, which heretofore have unnecessarily increas'd the number of Propositions and Demonstrations. 2. To encumber our work as little as we can with words we have made use, especially in our Analytick Calculus, of some Symbols, as \equiv for Equality, as also of \square and \square for Square and Rectangle, and of $\sqrt{\quad}$ the common Radicall sign for the square Root, with the Line $\sqrt{\quad}$ on the top for connecting of quantities together, the Root whereof is jointly taken, $\sqrt[3]{\quad}$ for the Cube Root, $\sqrt{\sqrt{\quad}}$ for the Biquadratick Root.

XX.

That the Reader may at one view see the Contents of the following Treatise, we have thought fit to present him here with it, by way of Synopsis. It is divided in two Books.

I.

The first whereof contains the chief and most select Propositions of Euclid's Elements, of Archimedes's Treatises of the Sphere and Cylinder, as also of the dimension of the Circle, &c. Wherein that which these Authors have demonstrated by a long and tedious Series of Consequences, and for the most part indirectly, we have here endeavour'd to Demonstrate directly, and so that the Demonstration of each Proposition depends, ei-
ther

Preface to the Reader.

either on no other, and so is evident by its own light, or on a very few of the antecedent ones.

II.

After the same way in the second Book we treat of the Conick Sections, and Demonstrate the chief properties of the Conoid, Spheroid, Cycloid, Conchoid and Spiral Lines, which are extant either in Apollonius or Archimedes and others, and what they have Demonstrated by long and tedious process's we have here exhibited in a short and easie Compendium. And that,

III.

In such a method, as does not so much require intent and severe thinking, as a bare and easie inspection, and application of the Principles of Specious Algebra, and method of Indivisibles. which yet,

IV.

We don't barely suppose, and remit our Readers to other Books to learn (which would be too troublesome) but in the Process of the Work it self, they are gradually, and as occasion presents, derived from their Original Fountain, and first Principles.

V

By the same way also the most useful and necessary Mathematical Praxes are laid down under the names of Corollaries and Scholia, the Construction of the Tables of Sines and Tangents taught, the Original and use of the Logarithms Demonstrated, and the Precepts both of Plain and Spherical Trigonometry deduced from their first Principles, &c.

VI.

The Praxis also of pure Arithmetick, and of common Decimal, and (which is seldom used) of Tetractical, as also the
Doctrine

Preface to the Reader.

Doctrine of Surds, are derived from their first Original. Whereunto,

VII.

As a Complement of the whole Work, we have added an Introduction to the Specious Analysis, or new Geometry of the Moderns, particularly according to the Method of Des Cartes, but much facilitated by later Inventions, and Comprizing the Precepts of the Art in six or seven Pages, but illustrated with above forty Examples in the different degrees of Equations.

What the Reader's opinion will be of these our Endeavours, design'd only for the use of young Students, time must teach us. The Author himself at least, amongst his other performances, allows these the first place.

MATHESIS

Mathesis Enucleata :

O R,

The Elements of the Mathematicks.

Book I.

Explaining the First Principles of the Mathematicks;
among which are (in the first place) *Definitions*,
and some *Consequeries* that flow from them.

C H A P. I.

*Containing the Definitions or Explications of the Terms
which relate to the Object of Mathematicks.*

DEFINITION I.

Mathematicks is the Science or Knowledge of Quantity, and of Beings, as far as they are subject to it, or measurable; and may justly claim the Name of *Universal*, while it is employ'd in Demonstrating those Properties which are common to all or most *Quantities*: But when it descends to the different Species of Quantity, and is busied in contemplating the Affections belonging particularly to this or that Quantity, it is distinguished by various Names, and distributed into various Parts, according to the various diversities of the Objects.

B

DEFINITION

DEFINITION II.

Quantity may be defined in General, whatever is capable of any sort of Estimate or Mensuration, as immediately the Habitudes and Qualities of Things, as *e. g.* the multitude of Stars in the Heaven, or of Souldiers in an Army, the length of a Rope, or Way, the weight of a Stone, the swiftness or slowness of Motion, the Price of Commodities, &c. but mediately, the very things themselves wherein those Estimable Qualities are inherent. Whence with the ingenious *Weigelius* we may not incongruously reduce them all to these four Kinds or Genders, *viz.* 1. to *Quanta Naturalia*, Natural Quantities, or such as Nature has furnish'd us with, as Matter with its Extension and Parts, the Powers and Forces of Natural Bodies, as Gravity, Motion, Place, Light, Opacity, Perspicuity, Heat, Cold, &c. 2. to Moral *Quanta* or Quantities, depending for the most part on the Manners of Men, and arbitrary Determinations of the Will; as for Example, the Values and Price of Things, the Dignity and Power of Persons, the Good or Evil of Actions, Merits and Demerits, Rewards and Punishments, &c. 3. to *Quanta Notionalia*, arising from the Notions and Operations of the Understanding, as *e. g.* the amplitude or narrowness of our Conceptions, universality or particularity, &c. in Logick; the length or brevity of Syllables, Accent, Tone, &c. in Grammar: And lastly, to *Quanta Transcendentia*, Transcendent Quantities, such as are obvious in Moral, Notional, and Natural Beings; as Duration, *i. e.* the Continuation of the Existence of any Being; which in Physicks especially is named *Time*, and may be conceived as a Line, &c. To these you may moreover add *Unity*, *Multitude* or *Number*, *Necessity* and *Contingency*.

DEFINITION III.

Number (whereon we shall make some special Remarks) if it be taken in the Concrete, is nothing else than an Aggregate or Multitude of any sort of Beings; taken abstractedly, it is, as *Euclid* calls it, *ποσάδος ποσότης*, a multitude, or (as they call it) *Quotity of Unities*, on the one hand Number, *i. e.* many are opposed to one; and in that sense Unity is not a Number:

ber: On the other hand Unity may be esteem'd a Number, since it is no less (if I may be allow'd that term) some *Quantity* than two or three. But as we denote or signifie particular Things, when we speak of them Universally, by the Letters of the Alphabet, A, B, C, (a, b, c,) &c. as universal Signs or Symbols of them; so for distinctly and compendiously Expressing the innumerable Variety of Numbers, Men have found out various Notes, the most natural whereof, are Points disposed in

particular extended Orders, as to denote Three, to denote Nine, &c. But that way which is most commodious for Practise, is by the common Notation, or Cyphers, 1, 2, 3, 4, 5, 6, 7, 8, 9. the invention whereof, as we have it by Vulgar Tradition, is owing to the *Arabians*. By a very few of these we express any number tho never so great, by a wonderful, tho now adays familiar, Artifice; the first Inventor of them having Establish'd this as an arbitrary Law, that the first of them shall signifie *unity* or *one*; the 2d *two*, &c. as often as they stand alone; but placed in a row with others, or on the left hand of one or more 0, or noughts, (which of themselves stand for nothing, but fill up empty places) if in the second, before a nought, they denote Tens; if in the 3d. Hundreds; in the 4th Thousands, in the 5th Myriads or Tens of Thousands; in the 7th so many Thousands of Thousands, or Millions; in the 8th Tens of Millions, &c. and so onwards, increasing always in decuple Proportion, by Tens, Hundreds, Thousands, &c.

COROLLARY I.

Hence you have a way of expressing or writing any Sum by these Notes, which you may hear expressed in Words; as it we were to express in Notes the year of our Lord, One Thousand Six Hundred Ninety and Nine, it is manifest, that according to the method above described, by placing 9 on the right hand in the first place, and nine again in the second towards the left, six in the third, and one or unity in the fourth, the business will be done. Thus it will be easie to any one with a little attention, to express any Number whatsoever by these Notes; (as suppose that which *Srenterus* proposes, in *Delic.*

Physico-Math. Part. 1. Probl. 75.) Eleven Thousand, Eleven Hundred, and Eleven.

COROLLARY II.

Hence you have also the Foundation and Reason of the Rule of *Numeration* in Arithmetick, or expressing any Numbers or Sum in Words, which you see written in Cyphers; which for greater ease may be done thus, *viz.* beginning from the first Figure towards the right hand, over every fourth Figure note a Point, (including always that which was last pointed) and at every second Punctuation or Point, draw short strokes thus ', one over the 2d, two over the fourth, &c. the first denoting Millions, the second Millions of Millions, or Bimillions, the third Trillions, &c. and the Intercepted Points the Thousands, in their kinds, &c.

SCHOLIION.

Here I cannot omit, on this occasion, what the forementioned *Weigelius* has hinted about another way of *Numeration*, and which *Dr. Wallis* mentions, *Oper. Mathemat.* Part 1. p. 25. & 66. shewing there a way (and illustrating it by Examples) of *Numeration*, and of Expressing the Figures; which proceeds thus; whereas now adays in numbring we ascend from unity or 1 to ten (the reason whereof; after which *Aristotle* makes a prolix Inquiry, *Probl. 3. Sect. 15.* was taken without doubt from the denary Number of our Fingers) if from unity we proceed only to four, (which *Aristotle* in the same place tells us some of the *Thracians* used to do of old,) and thence returning back again to Unity, we should proceed again after the same way; we might after that way obtain a vastly more simple and easie Arithmetick, than we have now adays. Which, even hence we may conclude; because for Multiplication and Division there would need no other Table (or *Pythagorick Abacus*) than this easie and short one:

1 . 1 . 1 once one is one;
 2 . 2 . 10 *i. e.* twice two are four;
 2 . 3 . 12 twice three are four and two.
 3 . 3 . 21 thrice three are twice four and one

And

Fig. 1.

And altho it is pity that we can't hope now a-days to substitute this vastly easier way of Computing, in room of the other now in use, because the other is universally receiv'd, and most sorts of Measures and other Quantities are fitted and accommodated to the decuple Proportion; yet it ought not to be altogether neglected in Mathematicks, which might receive very great advantage hereby, especially in Trigonometry, if the ingenious Invention of the Logarithms had not already supply'd its use therein. The whole Foundation of this *Tetradys* or *Quaternary Arithmetick*, is placed only in these three Notes, 1, 2, 3; so that any one of them alone, or in the first place, should denote Units, in the second place, *Tetrads*, or so many Fours (or *Quaternions*,) in the third place so many Sixteens, in the fourth place so many times Four Sixteens, or 64 s. &c. always proceeding in a Quadruple Proportion. For which way of Numeration there might be found out terms as commodious as those we now use, and which are thereby grown Familiar to us, as one, ten, twenty, a hundred, a thousand, &c. which will be evident by what follows:

One, <i>Unum</i>	1	One.	(Four,
Ten, <i>Decem</i>	10	<i>Quatuor, Tetras, a Quaternion</i> ^r or	
Twenty, <i>Viginti</i>	20	a <i>Biquaternion</i>	
Thirty, <i>Triginta</i>	30	a <i>Triquaternion</i>	
Hundred, <i>Centum</i>	100	a <i>Tetraquaternion</i>	
Thousand, <i>Mille</i>	1000	a <i>Quartan</i>	
Ten Thousand,	10000 &c.	a <i>Tetraquartan</i> , &c.	

DEFINITION IV.

A *Magnitude* is whatever is conceived to be Extended or Continuous, or has parts one without another, and contained within some common Term or Terms: wherein that is called a *Point* which is conceived (as indivisible, or) to have no Parts, and so no Magnitude, but is notwithstanding the beginning or first Principle of all Magnitude.

DEFINITION V.

IF we conceive a Point (A) (*Fig. 1.*) to be moved towards B, by this motion it will leave a trace, or describe the Magnitude

tude AB of one only Dimension, that is Length without Latitude, or which at leaſt we are to conceive ſo, and is called a *Line*: If that Line AB be conceiv'd again ſo to be moved, as that its extreme Points AB ſhall deſcribe other Lines BC and AD, it will deſcribe by that Motion the Magnitude AB CD, or (to denote it more compendiouſly by the Diagonal Letters) AC or BD, having both length and breadth, but without any depth or thickneſs, or at leaſt ſo to be conceived, and this is called *Superficies* or *Surface*: Laſtly, if this Surface AC be conceived ſo to move, *e. g.* upwards or downwards, that its oppoſite Points A and C again deſcribe other Lines AF and CH, and conſequently each of its Lines other Surfaces, &c. by this Motion there will be formed a Magnitude of three Dimensions, which we call a *Solid* or *Body*, which we will alſo denote by the two diametrically oppoſite Letters AH and DG. But as this Motion of the Point, Line, or Surface, may be various, ſo there will be produced by them various ſorts of Lines, Surfaces, and Solids: But theſe Productions ſtop here, and proceed no further; for the Motion of a Body can only produce another Body greater than the firſt, but no more new Dimensions.

CONSECTARYS.

I. **P**Oints therefore being moved thro' equal Intervals in the ſame or a like way or trace (*e. g.* in a ſtreight or the ſhorteſt trace) deſcribe equal Lines; and

II. The ſame or equal Lines moved thro' the ſame Right-lined or Curvilinear Paths, deſcribe equal Surfaces; and

III. Equal Surfaces moved according to the ſame Methods and Conditions deſcribe equal Solids: which, if rightly underſtood, are the firſt certain and infallible Foundations of the Method of Indivifibles. But here you muſt take care to diſtinguiſh between the way which the Line it ſelf deſcribes, and that which its Ends or extreme Points deſcribe: For altho *e. g.* the Point *a* (*Fig. 24.*) moves along in a more oblique way than A, and ſo deſcribes a longer Line *ac*; yet the Line *ab* deſcribes by a parallel Motion, an equal ſpace with the Line AB, (*viz.*) the ſame which the whole Line A b, whereof they are parts, would deſcribe. See *Faber's Synopſis*, p. m. 13.

DEFL.

DEFINITION VI.

BUT that we may a little further prosecute this Genesis of Magnitudes (as very much conducing to understand their Nature and Properties) if the Point A moves to B the shortest way, it describes the Right Line AB; but if in any (one) other it will describe the Curve or Compounded Line ACB: From whence, with *F. Morgues*, we may infer these

CONSECTARYS.

I. **T**HAT two Right Lines (*a*) beginning from the same Point A, and ending in the same Point B, will necessarily coincide, nor can they comprehend or inclose Space; for if they did, one must deviate, and so would cease to be a Right Line. (*a*) *Eucl. Ax.*
14.

II. In a Space comprehended by three Right Lines AB, BC, CA, (*a*) any two taken together, must needs be greater than any one alone. Moreover we may add this before hand;

III. In a Circle a Right Line drawn from A to B (*Fig. 3.*) will fall within the Circle, because the Curve Line ADB described, as we shall hereafter shew, being longer than a Right Line, must necessarily fall beyond it, or on the outside of it. And lastly,

IV. A Tangent, or Line (*b*) which does not cut or enter into the Circle, touches it only in one Point.

Moreover if a Right Line AB (*Fig. 4.*) move on another Right Line BC, remaining in the same Position to it, it will generate a *Plan Surface*, to which a Right Line being any way applied, will touch it with all its point, as *Faber* rightly describes it; if a Right Line be moved on a Curve, or a Curve on a Right Line, &c. they will generate a *Curve Surface*, call'd *Gibbous*, or *Convea* without, and *Concave* within.

DEFINITION VII.

IF a Right Line be fixed at one of its ends A, and the other be moved round (*Fig. 5.*) it will describe in this Motion a Circular

(a) *Eucl. 1. 1.*
Prop. 20.

(b) *Eucl. Prop.*
2. lib. 3.

Circular Plane, or a Circle; and by the motion of its end or extreme Point B, the *Periphery* or *Circumference* of that Circle BEF. The fixed Point A is called the Center of that Circle; the Lines AB, AC, &c. its *Radii* or *Semi-Diameters*; all of which are equal one to another. Any Right Line BC drawn from one part of the Circumference thro' the Center to another, is called the *Diameter*, and divides the Circle into two Semicircles BECB and BFCB. The Circumference of a Circle, whether great or small, is divided into 360 equal parts called Degrees, and each Degree into 60 Minutes, &c. From this Geniture of the Circle presupposed, there evidently follow these

CONSECTARYS.

I. **T**HAT 2 Circles which cut one another cannot have the same common Center; for if they had, the *Radii* ED and EA drawn from the common Center E (*Fig. 6.*) would be equal to the common *Radius* EB that is the part to the whole.

II. Nor can two Circles touching one another within side, have one and the same Center, for the same reason.

(a) *Eucl. 5 l. 3*
(b) & 6 of the
same Book.

(c) *Eucl. 3 l. 3.*

III. Of Lines falling from any given Point without the (*Fig. 7.*) Circle, and (c) passing thro' the Periphery to the opposite Concave part of it, that which passes through the Center of it, is the longest, *viz.* AB; and of the other that which is nearest to it is longer than that which is more remote: But on the contrary of those which fall on the Convex Periphery, that which tends towards the Center, as Ab, is the least, and the rest gradually greater, and there can be but two, as AE and AF, or Ae and Af, equal: All which will appear very evident by drawing other Circles from the Center A thro' B, D, E, and b, d, e. Or thus; having drawn two other Circles, from the Radii AB and Ab, if we conceive the Radii Ab and Cb to move towards the right hand, their ends will always recede further from one another; the same is also evident of the Radii AB and CB, moved also to the right together.

IV. Moreover (*Fig. 8.*) of all the Lines drawn within the Circle (a) the Diameter is the greatest, and the rest gradually less, by how much the more remote they are from the Center, &c.

Which

Which will be very evident to any one who contemplates a Circle inscribed in a Square, as also the Genesis of Curvity it self; as also many other ways which I shall now omit; or to mention one more thus; because the two Radii CA and CB being moved, in order to meet together, necessarily approach nearer to one another in their extreme Points.

DEFINITION VIII.

THE Aperture or opening of two Lines (Fig. 9.) AB, AD, &c. that are both fixed at one end at A, and the other ends opened or removed farther and farther from one another, is called an *Angle*, and usually denoted by 3 Letters, D, A, B, (whereof that which denotes the Angular Point, always stands in the middle,) and measured by the Arch of a Circle BD, or a certain number of Degrees which it intercepts. The greatest Aperture of all BAC is when the 2 Legs of the Angle AB and AC make one Right Line, and is measured by a Semicircle, or 180 Degrees. The mean or middle Aperture BAE or CAE, when one Leg EA is erected on the other AB or AC at Right Angles, so that it inclines neither one way nor the other, (thence called a *Perpendicular*) is named a *Right Angle*, whose measure is consequently a Quadrant (or quarter part) of a Circle or 90 Gr. Wherefore a Semicircle is the measure of two Right Angles: An Aperture or Angle BAD less than a Right Angle (and so measured by less than 90 degrees) is called an *Acute Angle*; and that which is greater than a Right Angle, as DAC (and so consisting of more than 90 degrees) is called an *Obtuse Angle*. Whence we may now draw these

(a) Prop. 15.
lib. 3.

COROLLARYS.

I. **T**WO or more Contiguous Angles (a) constituted on the same Right Line BC, and at the same Point A (as DAB, and DAC or DAB, DAE and EAC) make two Right Angles, as filling the Semicircle; and consequently,

(a) Eucl. 13.
lib. 1. with the
Coroll.

II. All the Angles that can be constituted about the Point A (as filling the whole Circle) are equal to 4 Right ones: As
also

also on the other side (a) if two Right Lines AB and AD meet on the same point A of another Right Line AC, and make the Contiguous Angles equal to 2 Right ones, that is, if they fill a Semicircle, BC will necessarily be the Diameter of a Circle, and consequently a Right line.

III. If one of the Contiguous Angles BAE be a Right one, the other CAE will be so also.

IV. If two Right Lines AB, CD, cut one another in E, the 4 Angles they make will be equal to 4 Right ones.

V. And as it is evident at first sight (Fig. 10.) that any Circle having one half (or Semicircle) folded on the other, at the Diameter ECD, the two Semicircles EHD, and EID, must needs agree, or every where coincide one with the other; so if the Angle ACD be supposed equal to the Angle BCD, that is, the Arch AD to the Arch BD, having one Leg CK or CL common; the others AC and BC being supposed before equal,

1. The Bases BL and AL, KB and KA, will be also equal; for these will coincide too, and therefore the Angles also.

2. The Line AB being bisected in K, the two Angles (c) at K will also coincide and be equal, and consequently

(a) *Euclid. 1.* frequently Right Angles: and contrarywise,

1. *Prop. 14.*

(b) *Eucl. 1. 1.*

4 & 3.

(c) *lib. III. 3.*

(d) *lib. 1. 5.*

3. The Angles at the Base of equal (d) Legs, CAB, CBA, and also those below the Legs, the Legs being produced to F and G, are equal.

4. Consequently the Spaces ACL and BCL, ACK and BCK are equal to one another.

5. The Contiguous Angles AED and BED insisting on equal Arches AD and BD are equal, and *è contra*; as also those that are not Contiguous, if their Vertex's are equidistant from E, &c.

6. It is hence also manifest, that a Perpendicular erected on the middle of any Line AB, inscribed in any Circle, passes through its Center, by what we have just now said; and if you likewise erect Perpendiculars on the middle of any 2 Lines, *ab* and *bm* (Fig. 11.) connecting any 2 Arches, or any 3 Points, *a*, *b*, *m*, that are not placed all in the same Right Line, those 2 Perpendiculars *ke*, *no*, will determine (by their Intersection) the Center of a Circle that shall pass through these 3 Points.

DEFINITION IX.

IF one Right Line DE cut or pass thro' another AB (Fig. 12) the opposite Angles at the top or intersection ACD and ECB are called *Vertical*; as also the other two ACE and DCB: Whence follow these

COROLLARYS.

I. **T**HAT the Vertical Angles are always (a) Equal; for both ACD and ECB with the third, ACE, which is common to both, fill or are equal to a Semicircle; as likewise both ACE and DCB with the third ECB, which is common. (a) *Eucl. lib. 1. 15.*

II. Contrarywise, if at (a) the Point C of the Right Line DE, the 2 opposite Lines AC and CB make the Vertical Angles x and z equal, then will AC and CB make one Right Line; for, since x and o make a Semicircle, and z and x are equal, by Hypoth. o and z will also make or fill a Semicircle, whose Diameter will be ACB.

III. By the same Argument it will appear, that of 4 Lines (b) proceeding from the same Point so as to make the opposite Vertical Angles equal, the 2 opposite ones AC and CB, as also DC and CE, will make each but one Right Line; for since all the 4 Angles together make a whole Circle, or 4 Right Angles, and the sum of x and o is equal (by Hypoth.) to the sum of o and z , it follows, that both the one and the other will make Semicircles, whose Diameter will be AB and DE, and so Right Lines. (a) *The same Prop. Schol. 1.* (b) *Schol. 2.*

DEFINITION X.

IN any Circle, a Right Line, as D.G, that subtends any Arch of it DGB, is called the *Chord* of that Arch (Fig. 13.) BF (a part cut off from the Semidiameter BC passing thro' the middle of the Chord) is called the *Sagitta* or *Intercepted Ax*, but most commonly the *Versed Sine*; and DF let fall from the other extremity of the given Arch BD, on the Semidiameter at Right Angles, is called the *Right Sine* of that Arch BD, or of the Angle BCD;

BCD; also DI is called the Right Sine of the Complement (or for brevity sake, Sine Compl.) of that Arch DH, or Angle DCH, &c. but the greatest of all the Right Sines HC let fall from the other extremity (or end) of the Quadrant (which is indeed the same as the Semidiameter of the Circle) is called the *whole Sine* or *Radius*; lastly, BE is called the *Tangent* of the Arch BD or Angle BCD, and CE its *Secant*: Whence Mathematicians, for the sake of Trigonometrical Calculations, have divided the whole Sine or Radius of the Circle into 1000, 10000, 100000, 1000 000, 10000 0000, &c. parts, thence to make a proportionable Estimate of the number of Parts in the Sine, Tangent, or Secant of any Arch, &c. as may be seen in the Tables of Sines, Tangents, and Secants. From these Suppositions and Explications of the Terms, we shall now infer from this Definition the following

C O R O L L A R Y S.

(a) Among the
rest Vid. Eucl.
28 & 29 lib.
3, and also part-
ly the 26 and
27.

I. **I**N equal Circles (and so much more (a) in one and the same) as the *Radii* or *Semidiameters* BC and *bc* are equal, so also it is evident, that the *Right Sines* DF & *Df*, of equal Arches BD and *bd*, or equal Angles BCD and *bcd*, also the *Tangents* BE and *be*, and *Secants* CE and *ce*, and *Subtenses* or *Chords* DG and *dg*, also the *Sagittæ* or *intercepted Axes* BF and *bf*, of double the Arches DBG and *dbg*, &c. will be equal, and so consist of an equal number of Parts of the whole Sine or Radius, &c. which both is evident from what we have said before, and may be further evinced, if one Circle be conceived to be put on the other, and the Radius BC on the Radius *bc*, that so they may coincide, by reason of the equality of the Arches BD and *bd*; and so of all the rest. And *e* contra,

II. In unequal Circles, the Sines, Tangents, &c. of equal Angles BCD or *bcd* (Fig. 14.) or similar Arches, or Arches of an equal number of Degrees, BD and *bd*, will be also similar or like, &c. *i. e.* the Sine *df* consists of as many parts of its *Radius bc*, as the Sine DF does of its Radius BC, &c. *e. g.* if the Radius BC be double of the Radius *bc*, each thousandth part of the one, will be double of each thousandth

sandth part of the other, but they are alike 1000 in each; because the degrees in the Circumference of the little one, particularly in the Arch bd are but half as big as those in the Arch BD , and yet equal in number in both. Thus also if the Sine DF contains 700 of the 1000 parts of its Radius BC , df will also contain 700 of the 1000 parts of its smaller Radius bc , and in like manner the Chords DG and dg , and the Tangents BE and be , &c. contain a like number of parts, each of its own Radius.

SCHOLI ON.

IT may not be amiss here to note by the by (altho it may seem more proper to be taught after the Doctrin of Proportions) that if, *v. g.* the degrees of a greater Circle be each of them respectively double, or triple, or quadruple, &c. of the degrees of a less Circle, according as the Radius of the one is double or triple to the Radius of the other, then, at least as far as Mechanical Practice can require, you may find the Arch of a greater Circle equal to the whole Periphery of a less, *viz.* if you take reciprocally that part of the greater Periphery, which shall be as the Radius of the less to the Radius of the greater, or as one degree of the less Periphery to one degree of the greater. *e.g.* if the less Radius bc be half the greater BC , and so also the Periphery, and each of the degrees of the one, be one half of the Periphery, and of each of the degrees of the other, one half of the greater Periphery will reciprocally be equal to the whole less Periphery, or 180 degrees of the one to 360 of the other, &c.

2. The same (at least in this case where the Radius cb is double of the Radius CB) may be done also Geometrically by the same reason. Having described Circles on each Radius, suppose the Radius CB (*Fig. 15.*) so to move with an equable motion about its Center c , as to take or move the Radius of the greater Circle cb along with it, and coming, *v.g.* to I. stops that also at 1, and going forward, to II. stops that again at 2, &c. Hence it will be manifest to any attentive Reader, that when the less Radius CB shall have described the Semicircumference $B. II. III.$ the greater Radius cb having moved to 3, will have described precisely a quarter of its circumference; and

and if still the less Radius C. IV. moves on to the right hand, and continues to carry the greater $c4$ along with it onwards the same way, it will necessarily follow, that in the same moment as the Radius C. IV. (together with $c4$.) shall come to its first situation in B, having described a whole Circle, the opposite Radius $c4$ will be come to 5, and have described half its Circle, having moved all along with an equal Motion. Hence it is evident, that the whole least Circle answers exactly to half the greater, and half of the first to a quarter of the last; as also the Quadrant B. II. to the Octant (or 8th. part) $b2$, &c. whence any Arch being given, as B. I. in the least Circle, if you draw thro' I the Radius of the greater Circle $c1$. you'll cut off an Arch $b1$. equal to the given Arch in magnitude, but only half in the number of degrees.

3. Hence follows naturally that celebrated Proposition of *Euclid*, that the Angle at the Center BC. I. or BC. II. is double of the corresponding Angle at the Periphery $bc.1$. or $bc.2$, &c. which in this case is manifest, and in the other 2 (*Fig. 16.*) of the wholes or remainders DCD and DPD it is also (a) certain; which is true also of the parts BCD and BPD to be

(a) *Eucl. p.* added or subtracted by the first Case.

20. l. 3.

(b) *Eucl. p. 9.*

l. 1.

4. Hence we have a new way of bisecting any given Angle CDE, or Arch CE (*Fig. 17.*) viz. if you make CB equal to the Leg DC, and from this, as Radius, describe an Arch BF equal to the Arch CE, and draw DF.

And with the same facility we might obtain the Trisection, if the greater Radius being triple to the less, was thus carried along by an equable Motion, as we have shewn how to do already in a double Radius; and this at first sight may seem very probable.

But whether the triple Radius be immediately carried round by the simple Radius CB, or by means of the double Radius cb , neither the one nor the other will cause an equable Motion. For in the latter Case, while the Radius cb describes the quadrant Bb, the Radius de will not describe so much as a Quadrant; but while cb with the same velocity describes the other Quadrant bf , the Radius de will come to g , describing an Arch as much greater than a Quadrant as the former

mer was less. In the former case on the contrary, the Radius CB moved on to D beyond a Quadrant, while de was carried from B to e , but if the Radius CD moving on, should again carry de along with it, the one would describe the same Arch eB , while the other would describe one less than before.

5. Hence the Angle at the Center ACE (Fig. 19.) upon the Arch AE , is equal to the Angle ADB at the Periphery, upon double that Arch AB .

6. Hence the Angle ADB in the Semicircle (Num. 1.) (a) is a Right Angle, in a Segment less than a Semicircle (Num. 2.) is an obtuse Angle, and (a) *Eucl. 31. lib. 2.* in a greater (Num. 3) an Acute one, because the Angle at the Center ACE upon the half Arch, is equal to the Angle ADB *pr. preced. 5.* and is a Right Angle in the first Case, Obtuse in the second, and Acute in the third.

7. Hence Angles in the same Segment, or (b) on equal Segments of equal Circles, or on the same or equal Arches, are all equal and *e contra.* (b) *Eucl. 26 and 27. lib. 3.*

DEFINITION XI.

When 2 or more Lines AB and CD are so continued as to keep always the same distance from one another (whose Genesis may be conceived to proceed from the uniform Motion of 2 Points A and C , always keeping the same distance from each other) they are called *Parallels*: But as it evidently follows from this Definition, that (a) those Lines which are Parallel to one third, are parallel to one another (since adding or subtracting equal Intervals to or from other equal ones, the sums or remainders must needs be equal :) so if the *Parallels* are Right Lines and cut transversely (or slopingly a-cross) by another Right Line EF , you'll have these (a) *Eucl. lib. 1. 30.*

COROLLARYS.

I. **T**HE Angles (b) which we call *Alternate* ones; GHK and HGI (Fig. 21.) are equal by *Corollary I. Definition X.* since the distances GK and HI , which are the Right Sines of the said Angles, are supposed equal. (b) *Eucl. lib. 1. 29.*

II. The

II. The External Angle EGA is also equal to the Internal opposite Angle GHK, by *Consect. 1. Definit. 9.* because that External Angle EGA is equal to the alternate Vertical one HGI.

III. The same Internal Angle GHK, with the other internal opposite one on the same side AGH (as well as the External one EGA, by *Coroll. 1. Definit. 8.*) are equal to two Right ones.

IV. On the contrary, If any Right Line EF (*a*) cutting
 2 others AB and CD transversly, makes the
 (a) *lib. 1.* alternate Angles GHK and HGI equal, their
Prop. 27 & 28 Right Sines, by *Consect. 1. Definit. 10.* will be equal, and consequently the Lines AB and CD parallel: and the same will follow, if the External Angle be supposed equal to the Internal, or the 2 Internal ones on the same side equal to 2 Right ones; since from either Hypothesis the former will immediately follow.

V. From whence it appears more than one way (*b*) That
 the 3 Internal Angles of any Triangle (e. g. H, G, K,
 (a) *lib. 1.* which will serve for all) taken together, are equal to
Prop. 32. two Right ones, and the External one GHD is equal to the two Internal opposite ones. For we might either conclude with *Euclid*, that 1, 2, 3, together make 2 Right ones, by *Consect. 1. Definit. 8.* but $2 = \text{II}$ and $3 = \text{III}$ pr. 1 and 2 of this, therefore I, II, III = 2 Right ones; or with others, 1, II, 4 are = 2 R. but $1 = \text{I}$ and $4 = \text{III}$ pr. 1st of this. Therefore, &c. or more briefly with *F. Pardies*, $1 = \text{I}$ pr. 1st of this, but 1, II, III, together = to 2 Right ones, by the 3d of this; therefore I, II, III = 2 R. Q. E. D.

DEFINITION XII.

IF a Right Line AB (*Fig. 22.*) be conceived to move from the top of a plain Angle CAD with a motion always parallel to its self, so that at one end A it shall always touch the Leg AC, and all along cut the Leg AD, while at length being come to F, it shall only touch that Leg with its other end B, and so fall at length wholly within the Angle CAD: It will describe by this motion within the Legs CAD the Triangular Figure EAF, and without them the Triangular Figure BAF; its parts within them *af* continually increasing, and the other without

fb continually decreasing; but with all its Parts, or the whole Line, it will describe the Quadrangular Figure *AEFB*: Consequently if the other Leg *AD* of the given Angle *CAD* (*Fig. 23.*) or any part of it *AB*, be moved along the other Leg remaining parallel to it self, it will also describe a Quadrilateral Figure, which will be also equilateral, if the Line describing it *AB*, be equal to the Line *AE* according to which it is directed; but if either of the Lines, as *AD* be greater than the other, the opposite Sides will be only equal; for the describent or describing Line is always necessarily equal to its self, and the Points *A*, *B*, *D*, moved with an equal Motion, describe also in the same time equal Lines *AE*, *BF*, *DG*. From these *Genesis* of Quadrangles and Triangles we have the following

CONSECTARIES.

I. **T**Hese Quadrilateral Figures are also Parallelograms, *i. e.* they have their opposite Sides Parallel; (a) because the Line that describes them is supposed to remain always parallel to its self, and the Points *A* and *D*, or *A* and *B*, to be always equidistant.

(a) *Schol. Prop. 34. lib. 1.*

II. Because the 2 Internal opposite Angles (b) *A* and *E*, and also *E* and *F*, &c. are equal to 2 Right ones, by *Consect. 3. Definit. 11.* if one Angle *v. g.* that at *A* be a Right one, all the others must necessarily be so too [in which case the quadrilateral and equilateral Figure *AF* is called a *Square*, and the other *AG* an *Oblong*, or *Rectangle*:] if there be no Right Angle, the opposite Angles transversly or cross-ways, *a* and *f*, or *a* and *g* are equal, because both the one and the other, with the third (c) make 2 Right ones [in which case the quadrilateral Equilateral *af* is called a *Rhombus*, but the other *ag* a *Rhomboid*].

(b) *The first part of the same Proposit.*

III. The Transversal (or Diagonal) Line (c) in any Parallelogram, divides it into two equal Triangles *AEF* and *FAB*; for all the Lines and Angles on each side are equal, and as the describent (Line) *AB* moved thro' the Angle *EAF* upon the Line *AE* described the Triangle *AEF*; so the Line *EF*, equal to the former, moved after the same way, thro' the Angle *AFB* also equal to the former Angle, upon the equal Line *FB*, must necessarily

(c) *the latter part of the same Prop.*

necessarily describe an equal Triangle; or, in short, all the Indivisibles $a f$, or their whole increasing Series, are necessarily equal to the like number of Indivisibles $f b$, increasing reciprocally after the same way.

IV. All Parallelograms that are between the same Parallels AB and CF (Fig. 24.) *i. e.* having the same Altitude (a) and the same or equal Bases, as CD or CD and $c d$,
 (a) lib. 1. are equal among themselves; for they may be
 Prop. 35 & 36 conceived to be described by the equal Lines AB and $a b$ equally moved thro' the same or equal Intervals of the Parallel Lines; so that all or each of the Indivisibles or Elements AB will necessarily be equal to all and each of the Indivisibles $a b$; for they all along answer one to the other both in number and magnitude.

SCHOLIUM.

HERE you have a Specimen of the Method of Indivisibles, introduced first by *Bonaventura Cavalierius*, and since much facilitated; and altho these Indivisibles placed one by another, or as it were laid upon an heap, cannot compose any Magnitude, yet by an imaginary Motion they may measure it, and as it were, after a negative way, demonstrate the Equality of two Magnitudes compared together, *viz.* if we conceive a certain number of such Elements in any given Magnitude, and thence conclude that in another consisting of the like Elements, ordered or ranked after the same way, there can be neither more nor less in number than in the first; thence follows their Equality, &c.

V. Hence therefore it is also Evident, that Triangles upon the same and equal Bases as CD and $c d$, and placed between the same Parallels, are necessarily equal, because they are the half of equal Parallelograms AD and $a d$, by the 3d Consequence of this Definition.

VI. *F. Mourgues* ingeniously concludes from hence, *viz.* because the 2 Internal opposite Angles (b) on the same side in any Parallelogram, are equal to two Right ones, and so all together equal to four; that therefore the three Angles of any Triangle ABC (Fig. 25. which may always be completed into a Parallelogram)

(a) lib. 1. Prop.

37 & 38, & 41.

(b) lib. 1. Prop.

22. otherwise.

Parallelogram) are equal to half of those four, or to two Right ones. This may be yet more briefly conceived thus; the Angles $b + c + d$ (the sum of the two inferiour ones) = to two Right ones; but $a =$ alternate d : therefore $b + c + a =$ to two Right ones, Q. E. D.

VII. Because it is manifest in Rectangular Parallelograms, if the Altitude AB, and Base BC (Fig. 26.) measured and divided by the same common Measure, be conceived to be (multiplied or) drawn one cross the other, that the * Area AC, thereby described, will be divided into as many little square Measures or Area's, as the number of their Sides multiplied together would produce Units; therefore the Area of any other Parallelogram will be after the like manner produced, if the Base be multiplied by the Perpendicular heighth, equally as if it were a Rectangle of the same Base and Altitude.

* This is manifest from its Genesis; for the five parts of the Line AB by its motion along the part of the Base BE, describes 5 little Squares, and moving along the following part, describes five more, &c.

VIII. Consequently also you may have the Area of any Triangle, by *Confectary* 3 and 5. if the Base be multiplied by half the Perpendicular heighth; or, the whole Base being multiplied by the heighth, if you take the half of the product.

DEFINITION XIII.

BUT as there are various Species of Triangles, while first with relation to their Sides, one is called *Equilateral*, as ABC (Fig. 27.) because all its Sides are equal; another *Equicrural* or *Isoceles*, as DEF, because it has two equal Sides DE and EF, while its Base DF may be either longer or shorter; and a third is called *Scalenum*, as GHI, because it has all its Sides unequal; then again in respect to their Angles, one is called *Rectangled*, as a, b, c , because it has one Right Angle at a ;

Another *Obtusangled*, as d, e, f , because it has one obtuse Angle at d ; a third is called *Acuteangled*, as g, h, i , because all its three Angles are Acute: So each of these kinds has its peculiar properties, which we shall partly hereafter demonstrate in their proper places, and partly deduce here as

CONSECTARYS.

I. **A**LL Equilateral Triangles are also Equiangular, and consequently Acutangled; for, having found a Center for three Points, and the Periphery A, B, C, (see Fig. 28.) by *Consect. 6. Definit. 8.* the three Arches AB, BC, and AC, answering to equal Chords; and consequently the three Angles at the Center O are equal, by *Consect. 1. of Definit. 10.* and therefore the three Angles at the Periphery also, as being half of the other, by the 3d *Consectary* of the same *Definition.* Each Angle therefore is one third part of two Right ones, by *Consect. 6. Definit. 12.* two thirds of one Right Angle, i. e. 60 degrees, and consequently Acute.

II. It follows also by the same Reason in an *Isoceles* Triangle, that the Angles at the Base opposed to equal Sides are equal, and (a) consequently Acute; for having circumscribed a Circle about it, equal Arches will correspond to the equal Chords DE and EF, and equal Angles at the Center DOE and FOE will correspond to them, and equal ones at the Periphery DFE, and FDE to these again. And it is evident that each of these are less than a Right Angle b. e. an Acute one, because all three are equal to two Right ones. Wherefore if the third is a Right Angle, the other two at the Base will necessarily be half Right ones.

(a) lib. 1.
Prop. 5. the
same otherwise
demonstrated.

SCHOLIUM.

WE will here (a) shew by way of Anticipation, the truth of the *Pythagorick Theorem*, esteemed worth an *Hecatombe*: Which hereafter we will demonstrate after other different ways; viz. In a Right Angled Triangle BAC (Fig. 29.) the Square of the greatest Side opposite to the Right Angle, is equal to the Squares of the other two Sides taken together. For having described the Squares of the other two Sides, AC d E, DE ab (taking ED = AB) and the Square of the greatest BC cb, it will be evident, that the parts X and Z are common to each, and that the two other Triangles in the greatest Square BAC and BDb, are equal to the two Triangles bac and Cdc which remain

remain in the two Squares of the lesser Sides; and so the whole truth of the Proposition will be evident, while these two things are undoubtedly true: 1. That the Side of the greatest Square Bb will necessarily concur with the Extremity of the less Db , and the other Side of the greatest Square Cc with its Extremity c , will precisely touch the Continuation of the Sides of the two least Squares dEa ; as you'll see them both expressed in the Figure. 2. The said two Triangles are every way equal; for the Angles at C with the intermediate one at Z , make two Right ones, therefore they are equal; but the Side CA is equal to the Side cd , and CB to Cc , and the Angles at A and d Right ones. Wherefore if we conceive the Triangle ABC to be turned about C , as a Center to the right hand, it will exactly agree with the Triangle Cdc , and the Point B will necessarily fall on the continued Line dE , as agreeing with the Line AB . Hence it is now evident, that $Ca = BD$, and because ba is also $= bD$, and the Angles at a and D Right ones. Where, if we conceive the Triangle bac to be moved about b as a Center, untill ba coincides with bD , and ac with DB , bc will also necessarily coincide with bB . Q. E. D.

To this Demonstration of *Van Schooten's*, which we have thus illustrated and abbreviated, we will add another of our own, more like *Euclid's*, but somewhat easier, which is this: Having drawn the Lines (as the other Figure 29 directs) the $\triangle ACD$ being on the same Base AC with the Square AI , and between the same Parallels, is necessarily one half of it, but it is also half of the Parallelogram CF being on the same Base with it, viz. DC ; therefore this Parallelogram $= \square AI$. In like manner $\triangle ABE$ is half the $\square AL$, and also half the Parallelogram BF , therefore $BF = \square AL$: therefore $CF + BF$ that is the \square of $BD =$ to the two $\square \square AI + AL$. Q. E. D. For because the Side BE occurs to, or meets the Side LK , and the Side CD the Side IH continued, it yet more apparently follows; because the Angles a and b , and also c and d , are manifestly equal, as making both ways, with the Intermediate x or z , Right Angles. Therefore the $\triangle BAC$ being turned on the Center B and laid on BLE will exactly agree with it, and turned on the Center C and laid on CID , will agree with that also, &c.

DEFINITION XIV.

ALL Rectilinear or Right Lined Figures that have more than three or four Sides (to the latter sort of which, there remains to be added another Species besides Parallelograms, call'd *Trapeziums*, whose Angles and Sides are unequal, as K, L, M, N, Fig. 30.) are called by one common Name *Polygons*, or *Many-sided* and *Many-Angled Figures*, and particularly according to the Number of their Sides and Angles, *Pentagons*, *Hexagons*, *Heptagons*, &c. All whereof, as also *Trapezia*, being resolvable into Triangles by Diagonal Lines, (as may be seen in the 31 and foregoing Fig.) you have these

CONSECTARYS.

I. **Y**OU have the Area of any Polygon by resolving it into Triangles, and then adding the Area's of each Triangle found by *Consect. of Definition 12* into one Sum.

II. The Area of the *Trapezium* KLMN (in the first of the Fig. 30) whose two opposite Sides, at least KL and MN, are Parallel, may be had more compendiously, if the Sum of the Sides be multiplied by half the common heighth KO.

S C H O L I U M.

HENCE we have the foundation of *Epipedometry* or Measuring of Figures that stand on the same Base, and Ichnography; in the Practise whereof this deserves to be taken special Notice of, that to work so much the more Compendiously, you ought to divide your Figure into Triangles, so that (Fig. 31.) 2 of their Perpendiculars may (as conveniently can be) fall on one and the same Base. For thus you'll have but one Base to measure, and 2 Perpendiculars to find the Area of both: But for Ichnography, the distance of the Perpendiculars from the nearest end of the Base must be taken; which we shall supersede in this Place and Discourse more largely on hereafter.

2. This resolution of a Polygon into Triangles may be perform'd by assuming a point any where about the middle, and making the sides of the Polygon the Bases of so many Triangles;

Triangles; (see the 2^d Figure mark'd 31) wherein it is evident; 1 That all the Angles of any Polygon are equal to twice so many right ones, excepting 4, as the Polygon has sides; for it will be resolv'd into as many Triangles as it has sides, and each of these has its Angles equal to 2 right ones. Subtracting therefore all the Angles about the Point M (which always make 4 right ones by *Conf.* 2. *Def.* 8.) there remain the rest which make the Angles of the Polygon. 2 All the external Angles of any right lined Figure (e, e, e, &c.) are always equal to 4 right ones; for any one of them with its Contiguous internal Angle is equal to 2 right ones *pr. Consect.* 1 of the said *Def.* and so altogether equal to twice so many right ones as there are Sides or internal Angles of the Figure. But all the internal Ones make also twice so many right Ones, excepting 4. therefore the external Ones make those 4.

DEFINITION XV.

AMong all these plain Figures those are call'd *Regular* whose Angles and Sides are all equal, as among trilateral Figures the Equilateral Triangle, among Quadrilateral ones, the Square, and in other kinds, several Species which are not particulariz'd by Names; but all others in whose Angles or Sides there is any inequality, are call'd *Irregular*: Tho' some of these also, and all the other may be inscrib'd in a Circle. Whence you have these

CONSECTARYS.

I. THE Areas of the Regular Figures may be obtained yet easier, if having found their Center (by *Consect.* 6. *Definit.* 8.) you draw from thence the Right Lines CB, CA, &c. (Fig. 32.) till there be form'd as many Triangles ACB, ACF, &c. as the Figure has Sides; for since all these Triangles have their Bases AB, BF, as so many Chords, and their Altitudes CD, CG, as so many parts of intercepted Axes DE and GH, and also equal *pr. Consect.* 1. *Definit.* 10. and so by *Consect.* 5. *Definit.* 10. are equal among themselves; one of their Area's being found and multiplied by the number of Sides, or half the Altitude by the Sum of all the Sides, you'll have the Area of the

C 4

whole

whole Polygon : For it is manifest from what we have already said, and very elegantly Demonstrated by F. Pardies, That any Regular Polygon inscribed in or circumscribed to a Circle, is equal to the Triangle AZa, one Legg whereof is equal to the Perpendicular height let fall from the Center upon any Side, and the other to the whole Periphery of the Polygon. Now if the Triangles into which the Polygon is resolved, do all stand on the same Right Line Aa, (Fig. 32.) and are all equal and of the same height, to which the Perpendicular AZ is equal, it will necessarily follow, that each pair of Triangles ABZ and ABC, BZF and BCF, &c. are equal among themselves, *pr. Consect. 5. Definit. 12.* and consequently the Sum of all the former will be equal to the Sum of all the latter, that is, the Triangle AZa to the Polygon given.

II. Since Regular Figures inscrib'd in a Circle, by bisecting their Arches AB, BF, &c. may be easily conceived to be changed into others of double the number of Sides, (as a Pentagon into a Decagon, &c.) and that *ad Infinitum*; a Circle may be justly esteemed a Polygon of infinite Sides, or consisting of an infinite Number of equal Triangles, whose common Altitude is the Semidiameter of the Circle : So that the Area of any Circle is equal to a Right Angled Triangle (as AZa) one of whose Sides AZ is equal to its (a) Semidiameter, and the other Aa to its whole Circumference.

(a) *Archimedes of the Dimen- sion of the Circle, Prop. I.*

SCHOLIUM.

IT may not be amiss to note these few things here, concerning the Inscription of Regular Figures in a Circle.

I. Having described a Circle on any Semidiameter AC, (a) (Fig. 33. N. 1.) that Semidiameter being placed in the Circumference, will precisely cut off one sixth part of it, and so become the Side of a Regular Hexagon : and so the Triangle ABC will be an Equilateral one, and consequently the Angle ACB and the Arch AB 60 Degrees, by *Cons. 1. Definit. 13.*

II. Hence a Right Line AD, omitting one point of the division B, and drawn (b) to the next D, gives you the Side of a Regular Triangle inscrib'd in the Circle, and

(b) *Eucl. 2d* subtends twice 60, i. e. 120 Degrees.

III. If the Diameters of the Circle AD and DE (N. 2.) cut one another at Right Angles in the Center C, the Right Lines AB, BD, &c. will be the Sides of an inscribed Square ABDE: For (c) the Sides AB, BD, &c. are the equal Chords of Quadrants, or Quadrantal Arches, and (c) *Eucl. 6. the Angles ABD, BDE, &c. will be all Right lib. 4.* ones, as being Angles in a Semicircle (*per Schol.* 6. *Definit. 10.*) composed each of two half Right ones, by *Consect. 2. Definit. 13.*

IV. *Euclid* very ingeniously shews us how to Inscribe a Regular Pentagon also, *Lib. 4. Prop. 10 & 11.* and also a Quindecagon (or Polygon of 15 Sides) *Prop. 16.* But though the first is too far fetch'd to be shewn here, yet (supposing that) the second will easily and briefly follow:

In a given Circle from the same point A (N. 3.) inscribe a Regular Pentagon AEF \overline{G} HA, and also a Regular Triangle ABC; then, will BF be the Side of the *Quindecagon*, or 15 Sided Figure. For the two Arches AE and EF make together 144 Degrees, and AB 120: (a) Therefore the difference BF will be 24, which is the 15th. part of the Circumference.

V. The Invention of *Renaldinus* would be very happy, if it could be rightly Demonstrated; (as he supposes it to be in his Book of the Circle) which gives an Universal Rule of dividing the Periphery of the Circle into any number of equal Parts required, in his 2d Book *De Resol. & Comp. Mathem. p. 367.* which in short is this: Upon the Diameter of a given Circle AB (*Fig. 34.*) make an Equilateral Triangle ABD, and having divided the Diameter AB into as many equal Parts, as you design there shall be Sides of the Polygon to be Incribed, and omitting two, *e. g.* from B to A, draw thro' the beginning of the third from D, a Right Line, to the opposite Concave Circumference, and thence another Right Line to the end of the Diameter B, which the two parts you omitted shall touch thus, *e. g.* for the Triangle, having divided AB into three equal parts, if omitting the two B2, thro' this beginning of the 3d you draw the Right Line DIII, and thence the Right Line III.B, which will be the Side of the Triangle; and so IV.B will be the Side of the Square, VB the Side of the Pentagon, &c.

N. B. The Demonstration of these (Renaldinus adds, p. 368.) we have several ways prosecuted in our Treatise of the Circle: Some of the most noted Antient Geometricians, have spent a great deal of pains in the Investigation and Effecton of this Problem, and several of the Moderns have lost both time and pains therein: Whence, we hope, without the imputation of Vain Glory, we may have somewhat obliged Posterity in this point.

DEFINITION VI.

IF the Plane of any Parallelogram AC (Fig. 25.) be conceived to move along a Right Line AE, or another Plane AF downwards, remaining always Parallel to its self; there will be generated after this way a Solid having six opposite Planes Parallel, two whereof, at least, will be equal to one another, whence it is called a *Parallelepiped*; and particularly a *Cube* or *Hexaedrum*, if the *Parallelogram* ABCD that describes it be a Square, and the Line along which it is moved, AE, equal to the Side of that Square, and Perpendicular to the describing Plane, and consequently all the six Parallel Planes comprehending this Solid, equal to one another. But if the describing or Plane Describent (Fig. 36.) be a Triangle or Polygon, the Solid is call'd a *Prism*, if a Circle, it is called a *Cylinder*. Now from the Genesis of these Solids you have the following

CONSECTARYS.

I. **I**F the Planes or Parallelograms Describent (a) ABCD and *abcd* (Fig. 37.) are equal, and their Lines of Motion AE and *ae* also equal; the Solids thereby described, viz. *Parallelepipeds*, *Cylinders*, and *Prisms*, (a) *Eucl. I. 11. p. 29, 30, 31* (which will therefore have their Bases and heights equal) will be equal among themselves; because the describent Indivisibles of the one, will exactly answer, both in number and position, to those of the other, as we have already shewn in Parallelograms; Consequently therefore,

II. Any *Parallelepiped* (b) may be divided by (b) *Eucl. I. 11. p. 28.* a Diagonal Plane BDHF (or a Plane passing thro' its Diagonals) into two equal *Prisms*; for by

Consect

Consect. 3. Definit. 12. the Triangles ABD and BCD, are equal, and are supposed to be moved by an equal Motion thro' equal spaces.

III. And since it is evident, even by this Genesis of them, that in Right Angled Cubes and Parallelepipeds, if the Base ABCD (Fig. 38.) being divided into little square Area's, be multiplied by the heighth AE, divided by a like measure for length, after this way you may conceive as many equal little Cubes to be generated in the whole Solid, as is the number of the little Area's of the Base multiplied by the number of Divisions of the side AE; you may moreover obtain the Solidity of any other Parallelepipeds, that are not Right Angled ones, by multiplying their Bases and Perpendicular Heights together.

IV. Moreover since every Triangular Prism is the half of a Parallelepiped, and any Multangular Prism may be resolved into as many Triangular ones, as its Base contains Triangles: you may obtain the Solidity (or Solid Contents) either of the one or the other, if you multiply the Triangular, or Multangular Base of them into their Perpendicular Heighth.

V. After the same manner you may likewise have the Solidity of a Cylinder, which may be considered as an Infinite Angled Prism, just as the Circle is as an Infinit-Angled Polygon.

DEFINITION XVII.

IF any Triangle ABC (Fig. 39. N. 1.) be conceived to move with one of its Plane Angles C, from the Vertex or top of a Solid Angle (determined by two Planes aAb and cAa joined together in the common Line Aa) with a motion always parallel to it self; so that its extreme Angular Point A shall always remain in the Line Aa, but with its Sides AB and AC shall all along raze on the two Angular Planes, till at length it falls wholly within the Solid Angle: by this its motion it will describe within the Solid Angle, the Figure we call *Pyramidal*, whose Base will be the Triangle *abc*, and its Vertex A will also describe without it another Quadrangular Pyramid, whose common Vertex will be the same A, but the Base the Quadrangle Cb, described by the Side of the moveable Triangle BC: The first Pyramid it will describe with its Triangular Parts, *αβγ* continually increasing

creasing from the point A, and ending in the Triangle abc ; but the latter Pyramid will be described by the remaining parts, continually decreasing downwards from the whole ABC, and the Quadrangular Trapeza $byds$ at length ending in the Right Line bc : So that in the mean while the said Triangle with its whole space describes, according to what we have said before, the Triangular Prism composed of those two Pyramids. From this Genesis of Pyramids you'll have the following

CONSECTARYS.

I. **O**F what sort soever the Describing Triangles are ABC, abc (N. 2.) so they are equal; and whatever the Solid Angles are, comprehended under the Planes abA , and acA , aba and aca , so they are accommodated to the Plane Angles A and \mathcal{A} , and such that, &c.

DEFINITION XVIII.

THere may be exhibited another easier Genesis of Cones and Pyramids, but it respects only the Dimension of the Surface, and not of the Solidity of them, viz. If you have a fix'd point A that is not in the Angular Plane BCDEF (Fig. 41.) and a Right Line AF let fall from that point to any Angle of the Plane, be conceived to move round the sides BC, CD, &c. This Plane by its motion will describe as many Triangles ABC, CAD, &c. as the Angular Plane has Sides. And these Triangles all meeting at the point A, make that Solid which we call a *Pyramid*. Now if instead of the Angular Plane there be supposed a Circular one, (or an Angular one of Infinite Sides) the Solid thence produc'd is called a *Cone*, whose Surface is equal to Infinite Triangles, constituted on the Base BCDE, and whose Solidity would consequently equal an Infinite Angled Pyramid of the same heighth. And after the same manner by the motion of the Line AF, remaining always Parallel to it self about Parallelograms or Triangular Planes, will be generated *Parallelipipeds*, *Prisms*, and *Cylinders*. But as one Pyramid will be produced more upright than another, according as the point A stands more over the middle of the Plane BCD, &c. (Fig. 42.) or respects

respects it more obliquely: So in particular a *Cone* is called a *right Cone*, when the line *AO* being let fall to the Center of the circular Plane (otherwise call'd the *Axis* of the *Cone*) constitutes on all sides right Angles with it; but it is call'd an *Oblique* or *Scalene Cone*, when the *Ax* stands obliquely on the *Base*. Which distinction may also be easily understood when apply'd to *Cylinders*, tho' a right *Cone* and *Cylinder* may also be conceiv'd to be generated after another way, as if for the one a *Triangle* and for the other a right angled *Parallelogram* *AOB* and *LAOB* be be conceiv'd to be moved round a line *AO* considered as immoveable (whence it is call'd an *Ax*;) and also a truncated *Cone* may be formed if a right angled *Trapezium*, 2 of whose Sides are parallel be moved, &c. And as we have deduc'd the Solidity of these Bodies from the foregoing Genesis, so their external Surfaces, as also of *Prisms* and *Parallelepipedes* may easily be found from the present Genesis, by any one who attentively considers the following

(a) *Archimedes*
lib. 1 de Con.
and Cylin. prop.
7. and 8.

COROLLARYS.

I. **S**ince the whole external Surface, except the *Base*, of any *Pyramid* is nothing but a *System* of as many *Triangles* *ABC*, *CAD* &c. as the *Pyramid* has *Sides*; if the *Area's* of those *Triangles* separately found by *Consect. 8. Def. 12.* be added into one *Sum*, you'll have the *Superficial Area* of the whole *Pyramid*.

II. If a *Pyramid* be cut with a Plane *b, c, d, e*, parallel to its *Base BCDE* (*Fig. 41.*) The Surface of that truncated *Pyramid* comprehended between the parallel Planes may be obtain'd if having found the Surface of the *Pyramid Abcde* cut off from the rest by *Consect. 1.* you subtract it from the Surface of the whole *Pyramid*.

III. The external Surface of a right *Pyramid* that stands on a regular *Polygon* *Base* is equal to a *Triangle*, whose *Altitude* is equal to the *Altitude* of one of the *Triangles* which compose it, and its *Base* to the whole *Circumference* of the *Base* of the *Pyramid*.

IV. Therefore the Surface of a right *Cone*, by what we have already said, is equal to a *Triangle* whose height is the side

ſide of the Cone, and the Baſe equal to the Circumference of the Baſe of the Cone.

V. The Surface of a truncated right Cone, or Pyramid is equal to a Trapezium which has 2 parallel Sides the loweſt of which is equal to the Periphery of the Baſe, and the other to the Periphery of the Top or upper Part, and the height, to the intercepted Part.

VI. The Surface of a right Cylinder or Priſm is equal to a Parallelogram which has the ſame height with them, and for its Baſe a right line equal to the Periphery of that Cylinder or Priſm.

DEFINITION XIX.

IF a ſemicircular Plane ADB (*Fig. 43. N. 1.*) be conceived to move round its Diameter AB which is fixt, as an Axis, by this Motion it will deſcribe a *Sphere*, and with its Semicircumference the Surface of that *Sphere*; every part whereof is equally diſtant from the middle Point of that Axis C (which is therefore call'd the Center of that *Sphere*.) Now if (*N. 2.*) this ſemicircular *Ambitus* (a) be conceived to be divided before that revolution, firſt into 2 Quadrants

(a) *Archimedes*
lib. 1. de Cono
& Cyl. Prop.
22. Coroll. &
Prop. 23.

AD, and BD, and then each of thoſe again into as many parts equal in Number and Magnitude as you pleaſe, and having drawn the Chords AF, FE, ED, &c. let the Polygon AFEDGHB Inſcribed in the Semicircle be conceived together with it to be turn'd about the Axis AB; then will A 1 F, and B 4 F deſcribe 2 Cones about the Diameters F f, and H h; and the Trapezia about the Axes 1, 2, 2 C, C 3, and 3 4, will deſcribe ſo many truncated Cones, and the lines AF, FE, &c. ſo many Conical Superficies, by the Antecedent *Def.* and ſo the whole Polygonal Plane AFEDGHB a Conical Body inſcribed in the *Sphere*, and contain'd under only Conical Surfaces. And as any attentive Perſon may eaſily perceive ſuch a Body to be leſs than the ambient *Sphere*, and its whole Surface leſs than the Surface of the ambient *Sphere*; ſo he may as eaſily trace theſe following

CONSECTAYS.

I. IF the Arches AF, FE, &c. be further bisected, and a Polygonal Figure of double the number of Sides inscribed in the Semicircle, and conceived to be moved round after the way we have already shewn, the Pseudoconical Body hence arising, will approach nearer and nearer to the Solidity of the Sphere, and the Surface of the one to the Surface of the other, and hence (if we continue this Bisection, or conceive it to be continued *ad Infinitum*) you may infer.

II. That a Sphere may be look'd upon as much a Pseudoconical Body, consisting of infinite Sides, and it's Surface will be equal to the infinite Conical Surfaces of that Body; which we will take further notice of below.

DEFINITION XX.

IF the Diameter AB of the Semicircular Plane ADB (*Fig. 43. N. 3.*) be conceived to be divided into equal Parts (as here the Semidiameter AC into 3.) and if the circumscribing Parallelograms CE, 2 E, 1 G on the transverse Parallels CD, 2 e, 1 f be conceived together with the Semicircle it self to revolve about the fixed Ax AB; it is evident that there will be formed from the Semicircle a Sphere as before, and from the Circumscribed Parallelograms, so many circumscribed Cylinders of equal heighth: but if all the Altitudes or Heights of these are bisected or divided into two, and so make the number of circumscribing Parallelograms double, there will be formed (by moving them round as before) double the Number of Cylinders of half the heighth, but which yet being taken together, approach much nearer the solidity and roundness of the Sphere, than the former, which were fewer in Number (*viz.* the six latter Parallelograms approach nearer to the Plane of the Circle than the three former) and thus if that bisection of the Altitudes be conceived to be continued *ad infinitum*, the innumerable Number of those infinitely little Cylinders will coincide with the Sphere it self. Moreover if you conceive any Polyedrous or Multilateral Figure to be circumscribed about the Sphere (which we here endeavour to delineate by the Polygon ABCD *N. 4.* circumscribed about the Circle)

cle) and the solid Angles thereof to be cut by other Planes *ab*, which shall touch the Sphere ; it is manifest there will thence arise another Polyedrous Figure, the Solidity whereof will approach nearer to the Solidity of the Sphere, and its Surface to the Spherical Surface than the former, and if the Angles of this be again in like manner cut off, there will still arise another new Solid, and new Surface approaching yet nearer to the Solidity and Surface of the Sphere than the former, &c. and so after an infinite Process they will coincide with the Sphere and its Surface themselves. Whence flow these

COROLLARYS.

I. **T**HE Sphere may be considered as a Polyedrous Figure, or as consisting of innumerable Bases, *i. e.* composed of an innumerable Number of Pyramids, all whose Vertex's meet in the Center, and so whose common heighth is the Semidiameter of the Sphere, and the sum of all the Bases equal to the Superficies of the Sphere.

II. If you can find a Proportion between a Cylinder of the same heighth with any Sphere, and whose Base is equal to the greatest Circle of that Sphere, and innumerable Cylinders circumscribed about it, as we have just now shewn ; then you may also obtain the Proportion between the said circumscribed Cylinder and the inscrib'd Sphere : Which to have here hinted may be of service hereafter in its proper place.

DEFINITION XXI.

THere remain those Bodies to be consider'd which are call'd *Regular*, which correspond to the Regular Plane Figures, and as those consist of equal Lines and Angles, so these likewise are comprehended under Regular and Equal Planes meeting in equal solid Angles ; and as those may be Inscribed and Circumscribed about a Circle, so may the latter likewise in and about a Sphere. But whereas there are infinite Species of Regular Plane Figures, there are only five of Regular Solids ; the first whereof is contained under four Equal and Equilateral Triangles, whence it is nam'd a *Tetraedrum* ; the second is terminated by six equal Squares, and thence is call'd *Hexaedrum*, and others

wise a *Cube*; the third being comprehended under eight Equal and Equilateral Triangles, is call'd an *Octaëdram*; the fourth is contained under twelve Regular and Equal Pentagons, and so is nam'd a *Dodecaëdram*; the fifth, lastly, is contained under twenty Regular and Equal Triangles, and is thence nominated an *Icosaëdram*. Besides these five sorts of Regular Bodies there can be no other; for from the concurrence of three Equilateral Triangles arises the Solid Angle of a *Tetraëdram*, from four the Solid Angle of an *Octaëdram*, from five the Solid Angle of an *Icosaëdram*; from the concurrence of four Squares you have the Solid Angle of an *Hexaëdram*; from that of three Pentagons you have the Solid Angle of a *Dodecaëdram*; and in all this Collection of Plane Angles, the Sum does not arise so high as to four Right ones. But four Squares, or three Hexagons meeting in one Point, make precisely four Right Angles, and so by *Consect. 2. Definit. 8.* would constitute a Plane Surface, and not a Solid Angle. Much less therefore could three Heptagons or Octagons, or four Pentagons meet in a Solid Angle, to form a new Regular Body; for those added together would be greater than four Right Angles. But now, for the Measures of these five Regular Bodies, take the three following

CONSECTARYS.

I. **S**ince a *Tetraëdram* is nothing else but a Triangular Pyramid, and an *Octaëdram* a double Quadrangular one, their Dimension is the same as of the Pyramids in *Schol. of Definit. 17.*

II. The Solidity of an *Hexaëdram* may be had from *Consect. 3. Definit. 13.*

III. A *Dodecaëdram* consists of twelve Quinquangular Pyramids, and an *Icosaëdram* of twenty Triangular ones, all the Vertex's or tops whereof meet in the Center of a Sphere that is conceived to circumscribe the respective Solids, and consequently they have their Altitudes and Bases equal: Wherefore having found the Solidity of one of those Pyramids, and multiplied it by the number of Bases (in the one Solid 12, in the other 20) you have the Solidity of the whole respective Solids.

D

DEFINITION

DEFINITION XXII.

BESIDES these Definitions of the Regular Bodies, we may also form like Idea's of them from their Genesis, which particularly *Honoratus Fabri* has given us a short and ingenious System of, in his *Synopsis Geometrica*, p. 149. and the following.

I. Suppose an Equilateral Triangle ABD to be inscrib'd in a Circle (*Fig. 44. N. 1.*) whose Center is C, whence having conceived the Radii CA, CB, CD, to be drawn, imagine them to be lifted up together with the common Center C, so that the point C ascending Perpendicularly, at length you'll have the Lines EA, EB, ED, equal to the Lines AB, BD, DA, After this way there will be generated, or made a Space consisting of four Equal and Equilateral Triangles, which is call'd a *Tetraëdron*. Hence we shall by and by easily demonstrate, the quantity of the Elevation CE, and the Proportion of the Diameter of the Sphere EF to be Circumscribed to the remaining part CF and so the reason of the Euclidean Genesis proposed *lib. 13. Prop. 13.*

II. Much like this, but somewhat easier to be conceived, is the Genesis of the *Octaëdron*, where by a mental raising of the Center C (*Fig. 44. N. 2.*) of the Square ABDE inscribed in the Circle, together with the Semidiameters CA, CB, CD, CE, until being more and more extended they at length become the Lines AF, BF, DF, EF, all equal among themselves, and to the side of the Square AB or BD; and its manifest, that by the like extension conceived to be made downwards to G, there will be formed eight equal and regular Triangles, which will all concur in the two opposite Points F and G. We might also deduce another Genesis of the *Octaëdron* from a certain Section of a Sphere, and also give the like of a *Hexaëdron* or Cube: but we have already given the easiest, of the one, and that which is also common to *Parallelepipeds*; and that of the other just now given is sufficient to our purpose.

C H A P. II.

Containing the Explication of those terms, which relate to the affections of the Objects of the Mathematicks.

D E F I N I T I O N XXIII.

EVery Magnitude is said to be either *Finite* if it has any bounds or terms of its Quantity; or *Infinite* if it has none, or at least *Indefinite* if those bounds are not determined, or at least not considered as so; as *Euclid* often supposes an *Infinite Line*, or rather perhaps, an *Indefinite* one, *i. e.* considered without any relation to its bounds or Ends: By a like distinction, and in reality the same with the former, all quantity is either *Measurable*, or such that some Measure or other repeated some number of Times, either exactly measures and so equals it, (which *Euclid* and other *Geometricians* emphatically or particularly call *Measuring*) or else is greater; or on the other side *Immense*, whose Amplitude or Extension no *Finite* Measure whatsoever, or how many times soever repeated, can ever equal: In the first Case, on the one Hand, the Measure (*viz.* which exactly measures any quantity) is called by *Euclid* an *aliquot Part* (*a*) or simply a *Part* of the thing measured: as *e. g.* the Length of one Foot is an aliquot Part of a Length or (*a*) *lib. 5.* Line of 10 Foot. In the latter Case the Measure (*Def. 1.* which does not exactly measure any Quantity) is called an *Aliquant Part*, as a line of 3 or 4 Foot is an *Aliquant part* of a Line of 10 Foot. Now therefore, omitting that perplext Question, whether or not there may be an infinite Magnitude, we shall here, respecting what is to our purpose, deduce the following

C O N S E C T A R Y.

EVery Measure, or part strictly so taken, is to the thing Measured, or its whole, as Unity to a whole number, for that (which is one) repeated a certain number of times, is supposed exactly to measure the other.

DEFINITION XXIV.

IF the same Measure measures 2 different quantities (whether the one can exactly Measure the other or not) those Quantities are said to be absolutely *Commensurable*; but if they can have no common Measure; they are called *Incommensurable*. Notwithstanding which they both retain one to the other a certain relation of Quantity, which is call'd *Reason* or *Proportion*, as we shall further shew hereafter. In the mean while we have hence, as an infallible Rule to try whether Quantities can admit of a Common Measure or not, this

CONSECTARY.

THose Quantities are Commensurable, whereof (a) one is to the other, either as Unity to an whole Number, or as one whole Number to another, for either one of them is the Measure of the other, as also of itself, and then it is so that other as Unity to some Number by the *Consect.* of the *preced.* or else they admit of some third Quantity for a common Measure which will be to either of them separately as Unity to some Number: therefore they are one to another as Number to Number.

(a) *Euclid lib.*
10. *Prop.* 5, 6,
7, 8.

DEFINITION XXV.

IF 2 Quantities of the same Kind, considered as Measures one of the other, being applyed one to the other, exactly agree or are exactly equal every way, (as *e. g.* 2 Squares on the same common Side, or two Triangles whose Lines Angles and Spaces exactly agree and conicide) or at least may be equally measured by a common Measure applyed to both) as *e. g.* a Square and an Oblong, or a Rhombus, or Triangle, each of whose Area's were 20 square Inches, altho' they do not agree in Lines and Angles; the first may be called *Simply Equal*, and the other *totally equal*, or *equal as to their wholes*: But if one be greater and the other less, they are *Unequal*, and that which exceeds is called the *greater*, and that which is deficient the *less*, and that

part by which the less is exceeded by the greater, in respect to the greater is call'd *Excess*, in respect to the less *Defect*, and by a common Name they are call'd the *Difference*. All which as they are plain and easy, so they afford us a great many self-evident Truths, which are used to be call'd Axioms, as these and the like

CONSECTARYS.

I. **T**He whole is greater than its Part, whether it be an Aliquot or aliquant Part.

II. Those Quantities which are equal to a third are equal betwixt themselves.

III. That which is greater or less than one of the equal Quantities is also greater or less than the other.

IV. Those Quantities which, being applyed one to the other, or placed one upon the other, either really or mentally, agree; may be esteemed as *totally equal*: And on the Contrary,

V. Those Quantities which are *totally equal* will agree, &c. To which might be added several others which we have already made use of and supposed as such in the preceding *Definitions*.

DEFINITION XXVI.

THere are moreover *Addition*, *Subtraction*, *Multiplication* and *Division*, which are common affections of all Quantities as well as of Numbers. *Addition* is the Collection of several Quantities (for the most part of one kind) into one total or Sum; which is either done so, that the whole (which is commonly called the *Sum* or *Aggregate*) obtains a new Name, or else by a bare connexion of the Quantities to be added by the Copulative *and*, or the usual Sign $+$ (*i. e.* *plus* or *more*) as for Example 2 Numbers . . . and : . . . (suppose 3 and 4) added together make the Sum (*i. e.* 7, or which is the same thing $3+4$;) and this Line _____ added to this other _____ gives the Sum _____ which is nothing but the 2 Lines joyn'd, or taken together. But now if we would treat of these Lines, or any other 2 Quantities to be added, more generally; by calling the first a (*a*) and the latter (*b*) we may fitly write their Sum $a+b$.

D 3

SCHO-

SCHOLIUM.

HAVING thus explained the Term of *Addition*, these and the like Axioms emerge of themselves: *If to equal Quantities you add Equal the Sum will be Equal; but if to Equal you add unequal the Aggregate will be unequal, &c.* Moreover it may not be amiss to admonish the Tyro of these 2 things. 1. In Addition may be seen the vast usefulness of that very Ingenious tho' familiar Invention mentioned in *Definit.* 3. for hereby we may collect into one Sum not only Tens, and Hundreds, but Thousands, Millions, Myriads, as tho' they were only Units; which we will Illustrate by an Example.

DEFINITION XXVII.

SUBTRACTION is the taking one Quantity from another (of the same kind;) which is so performed that either the remainder obtains a new Name, or by a bare separation of the Subtrahend by the privative Particle *less*, or the usual Sign — which stands for it, as e. g. . . . or three being subtracted from or 7, the remainder or difference is or 4 and this Line
 ——— Subtracted from that ——— leaves ———

Now if we would signify this more generally either of the Lines, or the Number above, or any 2 Quantities whatsoever that are to be Subtracted one from the other, by naming the first (*a*) and the latter (*b*) we shall have the remainder *a — b*. Herein are evident these and the like Axioms: *If from equal Quantities you Subtract Equal ones, the Remainders or Differences will be equal.* Here it will be worth while to take notice of, from this and the *preced. Definit.* the following

CONSECTARYS.

IF a negative Quantity be added to it self considered as positive (as -3 to $+3$ or $-a$ to $+a$) the Sum will be 0: for to add a Privation or Negative is the same thing as to Subtract a Positive, wherefore to join a Negative and Positive together, is to make the one to destroy the other.

II. If a negative be subtracted from its positive ($-a$ from $+a$) the remainder will be double of that positive ($+2a$) for to subtract or take away a privation or negative, is to add that very thing, the privation of which you take away; for really that which in words is called the *addition of a Privation*, is in reality a Subtraction, and a subtraction of it, is really an addition; and what is here call'd a *Remainder*, is indeed a Sum or Aggregate; and what is there call'd a *Sum*, is truly a *Remainder*. Thus,

III. If the positive Quantity ($+a$) be taken from the privative one ($-a$) the remainder is double the privative one ($-2a$) since, taking away a positive one, there necessarily arises a new Privation which will double that you had before. Hence,

IV. You have the Original of the Vulgar Rules in Literal Addition and Subtraction: *If the Signs of the unequal Quantities are different, in the room of Addition you must subtract, and in room of Subtraction add, and to the sum or remainder, prefix the Sign in the first place of the greatest, in the next of that from which you Subtract: but if the Signs are both the same, and the greatest quantity to be subtracted from the less, you must, on the contrary, subtract according to the natural Way, the least from the greater, and prefix the contrary Sign to the Remainder: Which Rules you may see Illustrated in the following Examples:*

Addition

$$4b - 2a$$

$$3b + 5a$$

$$7b + 3a$$

Subtraction.

from $2a + b$

Subst. $a - b$

R. $a + 2b$

from $3a + 2b$

Subst. $2a + 3b$

R. $a - b$

NOTE.

 Instead of the Authors 4th Consect. as far as it relates to Subtraction, which may seem a little perplext, take this general Rule for Subtraction in Species, viz. Change all the Signs of the lower Line, or Subtrahend, and then add the Quantities, and you have the true Remainder.

S C H O L I U M.

IN this Literal Subtraction, we have not that conveniency which the invention of Vulgar Notes supplies us with, that from the next foregoing Note we may borrow *Unity*, which in the following Series goes for 10, &c. This is done in *Tetractylal* Subtraction only with this difference, that an *Unit* here borrowed goes only for 4. That the easiness of this Operation may appear, we will add one Example, wherein from this number, — 1232002310232
you are to subtract this, 321012321223

310323323003

Whereever therefore the inferior Note is greater than the superiour one, the facility is much greater here than in common Subtraction, because never a greater number than 3 is to be subtracted out of a greater, than 4 and 2 : but if the inferior number be greater than the superiour, you borrow unity from the left hand, which is equivalent to 4; the rest is perform'd as in common Subtraction.

D E F I N I T I O N XXVIII.

Multiplication, generally Speaking, is nothing else but a Complex or manifold Addition of the same quantity, wherein that which is produced is peculiarly call'd the *Product*, and those quantities by which it is produced, are called the *Multiplicand* and the *Multiplier*: The first denotes the Quantity which is to be multiplied, or added so many times to its self; and the other the Number by which it is to be multiplied, or determines how many times it is to be added to it self. The same terms are applyed moreover to Lines and other Quantities. But here are two things to be chiefly noted; 1. That the Multiplication of one number by another, or of a Line by a Line, may be considered as having a double Event; for the Product may be either of the same or a different kind, as, e. g. when 4 is multiplied by 3 . . . the product may be considered either as a Line, thus, or as

a Plane Surface in this Form, Whence it is also

named a Plane Number, and the product is conceived to be formed by the motion of an erect Line AB, consisting of 3 equal parts, along another BC, consisting of 4 equal parts, and conceived as lying along. So also the Multiplication of Lines (*e.g.* of the Line A ——— B by the Line B ——— C) may be conceived to be so performed, that the Product also shall be a Line, *e.g.* C ——— D (concerning the usefulness of which Multiplication in *Geometry*, we shall have occasion to speak more hereafter;) or so, that the Product shall be a Plane or Surface, arising from the motion of the erect Line AB, along AC, conceiv'd as lying along; as we have already shewn. But as for the most part these Planes so produced are called *Rectangles*, if the Lines that form them are unequal; but if they are equal they are call'd *Squares*, (otherwise the Powers of the given Quantities;) and in this case the Lines that form them are called *Square Roots*; so also if those Planes are multiplied again into a third Quantity (as either a Line or a Number) there will arise *Solids*, and particularly if that third Quantity be the Root of the Square, the Product is called a *Cube*, &c. The other thing to be noted is, That both these ways of Multiplying either Numbers or Lines, are expressed by a very compendious, tho arbitrary way, of Notation, *viz.* by a bare *Juxtaposition* of the Letters which denote such and such Species of Quantities, as, *e.g.* if for the forementioned Number or Line AB we put *a*, and for BC *b*, the Product will be *ab*; or if the Efficients are equal, as *a* and *a* the Square thence produced, will be *aa* or *a²*; and if this Square be further multiplied by its Root *a*, then the Cube thence produced will be *aaa* or *a³*, &c. Which being premised, you have these following

CONSECTARIES.

I. IF a Positive Quantity be multiplied by a Positive one, the Product will be also Positive; since to multiply is to repeat the Quantity according as the Multiplier directs: Wherefore to multiply by a Positive Quantity, is to repeat the Quantities positively; as on the other side, to multiply by

a Privative, is so many times to repeat the Privation of that Thing: Which we shall shew further hereafter.

II. Equal Quantities (a and a) multiplied by the same (b), or contrariwise, will give equal Products (ab and ab or ba).

III. The same Quantity (a) multiplied by the whole Quantity ($a + b + c$) or by (a) all its parts separately, will give equal Products. Also

(a) *Eucl. lib.*

2. *prop. 1.*

(b) *lib. 2.*

prop. 2.

IV. The whole ($a + b$) whether it be multiplied by (b) it self, or by its parts separately, will give equal Products.

SCHOLIUM I.

THE Vulgar Praxis of Numeral Multiplication, is founded on these two last Confectarys, as *e. g.* to multiply 126 by 3; you first multiply 6 by 3, then 2, *i. e.* 20 by 3, then 1, *i. e.* 100 by the same, and then add each of those partial Products into one Sum: In like manner being to multiply 348 by 23, you first multiply each Note of the Multiplicand by the first of the Multiplier (3) and then by the second (2) (*i. e.* 20) &c. which is to be done likewise after the same manner in Tetractical Multiplication; only in this latter, which is more easie, you have nothing to reserve in your mind, but all is immediately writ down, (which might also be done in Vulgar Multiplication) as may be seen by this Example underneath, as also the great easiness of this sort of Multiplication, beyond the common way, because there is no need of any longer Table than that we have shewn page 7.

 120020322
 \end{array}$$

SCHO-

SCHOLIUM II.

It is manifest from what we have said,

I. IF the Base of a Parallelogram be called (b) and its Altitude a , its Area may be expressed by the Product ab , by *Conf.* 7. *Definit.* 12.

II. If the Base of a Δ be b or $e b$, and its Altitude a its Area will be half ab or half $e ab$, by *Confectary* 8. of the same *Definition*.

III. If the Base of a Prism or Parallelepiped or Pyramid be half ab or ab , and its Altitude c , the solid Contents of that Prism will be half abc , and of the Parallelepiped abc , by *Consect.* 3 & 4. *Def.* 16. and of the Pyramid $\frac{1}{3}abc$, by *Conf.* 3. *Def.* 17.

DEFINITION XXIX.

Division, in general, is a manifold or complicated Subtraction of one quantity (which is called the *Divisor*) out of another (which is called the *Dividend*) whose multiplicity, or how many times the one is contained in the other, is shewn by another quantity arising from that Division, which is therefore called the *Quote* or *Quotient*. Here also the *Divisor* is of the same kind with the *Dividend*, or of a different kind, *e. g.* of the same kind if the product (12) be divided by (3) whence you'll have the Quotient (4) or dividing the aforementioned Line CD by the Line AB you'll again have the Line BC; but of a different kind, if the plane number a-

bove found or the Rectangle ABCD be divided by

a Retroduction, or a moving backwards again the erect Side AB, by whose motion the Rectangle was first formed, that so the Line BC may remain alone again. But both these kinds of Division as they have their peculiar Difficulties in Arithmetick and Geometry, which we shall further elucidate in their proper places; so they may be universally and very easily performed in Species (or by Letters) which will be sufficient to our present purpose; or by a bare separation of the Divisor from the Dividend, if it be actually therein included; or by placing

placing the Divisor underneath the Dividend with a Line between. Thus if ab be to be divided by (b) the Quotient will be a ; if by a , the Quotient will be (b) ; but if a or ab be to be divided by c which Letter since it is not found in the Dividend, cannot be taken out of it) the Quotients are $\frac{a}{c}$ and $\frac{ab}{c}$ i. e. a or ab divided by c , after the same manner as if 2 were to be divided by 3; which Divisor, since it is not contained in the Dividend, is usually placed under it, by a separating Line thus, $\frac{2}{3}$, 2 divided by 3.

S C H O L I O N.

HOW difficult Common Division is, especially of a large Dividend by a large Divisor, is sufficiently known: but how easily it is performed by TetRACTICAL Arithmetick, we will barely bring one Example to shew. If the Product found in *Schol.* 1. of the preceding *Definition*, 120020322 be again to be divided by its Multiplier 133, it may be performed after the usual way, but with much more ease, as the following Operation will shew; or according to a particular way of *Weigelius*, by writing down the Divisor, and its double and triple, in a piece of paper by it self, after this way:

1 2 3	3 1 2	1 1 0 1
Divisor,	Double,	Triple.

and then moving that piece of Paper to the Dividend, note, which of those three Numbers comes nearest to the first Figures of the Dividend; for that barely subtracted gives the Remainder, and will denote the Quotient to be writ down in its proper place; as the operation itself will shew better than any words can.

```

Thus

Thus after *Weigelius's* way:

$$\begin{array}{r|l} 2 & \\ \times 2 & \\ \hline 33 & 6.44 \\ \times 200 & \times 03.22 \end{array} \quad 321032.$$

DEFINITION XXX.

Extraction of Roots is a Species of Division, wherein the Quotient is the Root of the given Square or Cube, &c. But the Divisor is not given, neither is it all along the same (as it is in Division) but must be perpetually found, and they are several. And as the Squares of Simple Numbers 1, 2, 3, &c. viz. 1, 4, 9, 16, &c. and their Cubes 1, 8, 27, 64, &c. may be had immediately out of a Multiplication Table, as also their Roots, without any further trouble; and likewise in Species, as the Roots of the Square aa or a^2 , or of the Cube aaa or a^3 , are without doubt (a); so if the Square Root be to be extracted out of de , or the Cube Root out of fgm (because the letters are different, and no one can be taken for the Root) the Square Root is commonly noted by this Sign \sqrt{de} , the Cube Root by this $\sqrt[3]{C}$, or $\sqrt[3]{fgm}$, &c. as also in Numbers that are not perfect Squares (as e.g. 2, 3, 5, 6, 7, 8, 10, 11, 15, 17, 19, &c.) we can no otherwise express the Square Roots, then after this manner $\sqrt{2}$, 7, $\sqrt{19}$, &c. and in those that are not perfectly Cubical (as all between 1, 8, 27, 64, &c.) we can only express their Cube Roots after some such manner, $\sqrt[3]{c. 7}$, or $\sqrt[3]{7. \sqrt{c. 61}}$, or $\sqrt[3]{61}$ &c.

Which forms of Roots in specious Computation, we call *Surd Quantities*, in Vulgar Arithmetick *Surd Numbers*, i. e. such as cannot be perfectly expressed by any Numbers; altho we have Rules at hand to determine their Values nearer and nearer *ad Infinitum*.

These Rules accommodated to Square and Cube Numbers, &c. which otherwise are more difficult to be comprehended, appear plain and easie to him, who multiplies a Root expressed by

by 2 Letters (called therefore commonly a Binomial) first Quadratically, then Cubically, &c. For he will have as

CONSECTARYS.

I. **T**HE Square of any assumed Root, as also, *Prop. 4. lib. 2. Eucl.* and at the same time a general Rule for Extracting the Square Root, all expressed in these few Notes :

$$a a + 2 a b + b b.$$

II. The Cube of the same Root, a New Theorem, and at the same time a Rule for Extracting any Cube Root, contained in this Theorem :

$$a^3 + 3 a a b + 3 a b b + b b b.$$

SCHOLIUM I.

WHich that we may more plainly shew, especially as far as it relates to the Rules of Extraction, consider, 1. That the Root of the Square $a a + 2 a b + b b$ is already known (for we assumed for the Root the Quantity $a + b$) so that now we are to see which way this Root is to be obtain'd out of that Square by Division. It will presently appear, that the first Note of the Root a , will come out of the first part of the Square $a a$, and the other part b must be obtain'd out of the remainder $2 a b + b b$; and so as there are 2 Notes of the Root, the Square must be distinguish'd as it were into 2 Classes, each of which gives a particular note of the Root. Then it is manifest, that the first Note of the Root (a) may be obtain'd out of the Square $a a$ by a simple Extraction. Now it is evident, if I would have by Division the other Note of the Root, the next following part of the remaining Classis must be divided by $2 a$, the double of the Quotient just now found, and that nothing should remain after this Division (for now we have the whole Root $a + b$) you must not only subtract the Product of the Divisor and this new Quotient, but also the Square of this new Quotient: Which is the Vulgar Method and Rule for the Extraction of Square Roots taught in common Arithmetick.

Likewise

Likewise if you would extract the Root of the above-mentioned Cube, which we already know, having formed it from $a+b$, it is manifest, that the first Note of the Root a will come out of the first part of the Cube a^3 , and the other b , must be obtain'd out of the remainder $3abb+b^3$, and so, as there are two Notes of the Root, the Cube must be distinguish'd, as it were into two Classes, each of which will give a particular Note of the Root. Now it is manifest, the first Note of the Root a is obtained by simple Extraction of the Root out of the Cube aaa . It is moreover evident, if I would have by Division the other Note of the Root b , the next remaining part must be divided by $3aa$ (the triple Square of the precedent Quotient, or thrice the precedent Quotient multiplied by it self) and, that nothing should remain after this division (for now we have the whole Cube Root $a+b$) you must not only subtract from the remaining Dividend the Product of the Divisor, and the new Quotient ($3aab$, but also the Product of the Square of the new Quotient, and thrice the precedent Quotient ($3abb$) and moreover the Cube of that new Quotient b^3 : Which is the Method of extracting Cube Roots in Vulgar Arithmetick.

SCHOLIUM II.

FROM what we have said you have also the Reason of another rule in Arithmetick which teaches how to approach continually nearer and nearer to the Square and Cube Roots of numbers that are not exact Squares and Cubes; viz. by adding to the given Number perpetually new Classes and Cyphers or 0's, two at a time, to the Square, and three to the Cube, and so continue on the operation as before; which will add Decimal Parts to the Integrals before found; and the next operation (if you add a second Classe of Cyphers) will exhibit Centesimal Parts, and so on *ad Infinitum*. For Example, If I would have the Square Root of 2 pretty near, I can assign no nearer whole Number than 1. But by adding a new Classe of 2 Cyphers, i.e. multiplying the given Number by 100 (whereby the Root is multiplied by 10) you'll have 14, nearly the Root of 200, that is, $\frac{14}{10}$ or $1\frac{4}{10}$ much nearer the Root of 2 than the former; and thus you may always come nearer and nearer *ad Infinitum*, but never to an exact Root. For if you could have the

the exact Root of 2, or 3, or 5, &c. in any Fraction whatsoever, that Fraction must be of such sort, that its Numerator and Denominator being squared, the Fraction thence arising must exactly equal 2 or 3, or 5, &c. that is, its Numerator must be exactly double, or triple, or Quadruple, &c. of the Denominator; which can never be, because both are Squares, and in a Series of Squares no such thing can happen. Hence you have these

CONSECTARYS.

III. **T**hat it is a certain mark of Incommensurability, if one quantity is 1, and other the $\sqrt{2}$, or $\sqrt{3}$, or $\sqrt{5}$, &c.

IV. That these sorts of Quantities are notwithstanding Commensurable in their Powers, *i. e.* their Squares are as 1 and 2, or as a number to a number.

V. Those Quantities which are to one another, as 1 and $\sqrt{2}$, or as $\sqrt{2}$ and the $\sqrt{2}$ are incommensurable in Power also. Which being rightly understood, you may easily comprehend several (a) Propositions of *lib. 10 Eucl.* especially after some few things premised concerning Reason and Proportion.

SCHOLIUM. III.

From what we have shewn may easily be concluded, that to any proposed Quantity whatsoever, which *Euclid* calls (b) *Rational*, and for which we may always put 1, there may be several others both commensurable and incommensurable, and that either simply or in power so; those which are commensurable to a Rational given Quantity, either Simply or only in Power (which, *e. g.* are to it, as 2, 3, 4, &c. $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. or as $\sqrt{2}$, $\sqrt{3}$, $\sqrt{4}$, $\sqrt{\frac{1}{2}}$, $\sqrt{\frac{1}{3}}$, $\sqrt{\frac{1}{4}}$, &c.) are called also *Rational*: but those which are Incommensurable both ways (*i. e.* both simply and in power) as ($\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, &c.) are called *Irrational*. In like manner the Square of a given Rational Quantity (as 1) is called Rational, and Quantities commensurable to it (as 2, 3, 4, 5, &c. $\frac{1}{2}$, $\frac{1}{3}$, &c. \square) are called also *Rational*; but incommensurable ones ($\sqrt{2}$, $\sqrt{3}$, $\sqrt{5}$, &c.) *Irrational*, and the Sides and Roots of them more *Irrational*.

(a) *Eucl. lib. 10, Prop. 9, 10, 11, 12, 13 &c.*
(b) *lib. 10, Def. 5, 6, 7, 8, 9, 10, 11*

DEF.

DEFINITION XXXI.

Any Quantities whatsoever of the same kind, whether commensurable or incommensurable, equal or unequal, admit of a twofold respect or relation of their magnitude, one whereof, when only the difference or excess of one above another is respected (as 10 which is 3 more than 7) is called an *Arithmetical Reason* or *Respect*; the other, wherein respect is rather had to the Amplitude, whereby one is contained once, or a certain number of times in the other (as 3 is contained thrice in 10 and $\frac{1}{3}$ part more) is called *Geometrical Reason*, or by way of Emphasis, only *Reason*, and by others *Proportion*; and this Reason or Proportion, if the less is exactly contained a certain number of times in the greater (as 3 in 6, or 4 in 12) is generally called, on the part of the greatest term, *Multiple*, and on part of the less, *Submultiple*, and particularly in the first Example *double*, when 6 is taken in respect to 3, and *subduple* when 3 is taken in respect to 6; in the other *triple* and *subtriple*, &c. If the less be contained in the greater once or more times, unity only remaining over and above (as 3 in 4 and 4 in 9) the Reason or Proportion is called *Superparticular* and *Subsuperparticular*, and is noted by the terms *Sesqui* & *Subsesqui*, joyning the ordinal Name of the lesser Term; as the Reason of 4 to 3 is called *Sesquitertian*, and contrariwise *Subsesquitertian*; the Reason of 9 to 4 is called double *Sesquiquartan*, and contrariwise *Subduple Subsesquiquartan*, &c. If lastly, the less be contained in the greater once, or a certain number of times, several units remaining over and above, it is commonly called *Superpartient* Reason and is expressed by the word *Super* or *Subsuper*, joyned with the adverbial Name of the remaining Parts, and the ordinal Name of the lesser Term; thus, e.g. the Reason of 7 to 4, is called *Supertriquartan*, 12 to 5 double *Superbiquintan*, &c. but when the Quotient arises by the division of the greater term by the less, and is commonly expressed in the same words, it is also commonly called by the name of *Reason* (e.g. 2 is the name of the Reason of 6 to 3, $2\frac{1}{4}$ of 9 to 4, or contrariwise, &c.) as also the quotient arising by division of the Consequent by the Antecedent (as $\frac{1}{2}$ in the first case, $\frac{4}{9}$ in the latter) by which name the antecedent Term of the Reason being multiplied, produces its Consequent; which is evident by naming any Reason

e or i , or o , &c. Thus if the antecedent Term be called a or b &c. the Consequent may be rightly call'd ea or eb , oa or ob , &c. and because in an Arithmetical Relation we only respect the excess of the first above the following, or of the following above the foregoing (which may be called x or z) if the antecedent (which may be called a or b) be less, the consequent may properly be called $a+x$ or $b+z$; but if it be greater, the other will be $a-x$ or $b-z$.

CONSECTARYS.

I. **W**E may hence readily infer, that if the Diameter of any Circle be called a the Circumference may be called $e a$, (for whatever the proportion is between them, it may be expressed by the Letter e) and the Area, according to *Consectary 2. Definition 15*, will be $\frac{1}{4} e a a$.

II. If for the Base of any Cylinder or Cone you put $\frac{1}{4} e a a$ and the Altitude (b) the Solidity of that Cylinder may be rightly expressed by $\frac{1}{4} e a a b$, by *Consect. 5. Definit. 16*, and of the Cone by $\frac{1}{2} e a a b$, by *Consect. 4. Definit. 17*.

DEFINITION XXXII.

AS the Identity (or sameness) of several Geometrical Reasons used to be called *Geometrical Proportionality*, or emphatically *Proportion*; so the similitude (or likeness) of several *Arithmetical Reasons*, is deservedly call'd *Arithmetical Proportionality*, or by a particular Name *Progression*; and consequently those *Progressionals*, or *Arithmetical Proportionals*, which exceed one another by the same difference, either uninterruptedly or continually as 2; 5, 8, 11, 14, &c. ascending, or 30, 28, 26, 24, 22, 20, &c. descending; or interruptedly, as 2 and 5, 7 and 10, 11 and 14, &c. ascending; or 30 and 26, 24 and 20, 18 and 13, &c. descending: For which, and all other in what case soever, we may universally put this (or such like) continual Progression, v. g. $a, a+x, a+2x, a+3x$, &c. ascending; or $a, a-x, a-2x, a-3x$, &c. descending, but in an interrupted Progression, v. g. b and $b+z$ and c and $c+z$, c and $c-z$, d and $d-z$, &c. descending. Whence you have this

CON

II.

CONSECTARY.

ANY Difference being given, the following Terms of the Progression, continually proceeding from the first assumed or given one, may be found; as also several Antecedents that interruptedly follow the given or assumed ones, viz. by adding or subtracting the given Difference to or from the former Terms to find the latter.

DEFINITION XXXIII.

IN like manner, since *Reasons* are said to be the same, which have the same Denomination of Reason, those quantities will be proportional which continually ascend by the same denomination of Reason, as 2, 4, 8, 16, 32, 64, &c. or descend, as 81, 27, 9, 3, 1. there by the Denomination of the Reason 2, here 3; or that ascend interruptedly, as 2, 4; 3, 6; 5, 10, &c. or descend, as 40, 10; 28, 7; 20, 5; 8, 2, &c. Whence you have these

CONSECTAYS.

HAVING two Terms given, or only one with the Denomination of the Reason (e.g. the Term 2 with the Denomination of the Reason 3, or universally the first Term *a* with the Denomination of the Reason *e*) it will be easie to find as many more Terms of the Geometrical Progression or Proportion as you please, viz. by always multiplying the Antecedent by the Denomination of the Reason, that you may have 2, 6, 18, 54, &c. or $a, e a, e^2 a, e^3 a, \&c.$ in continued, or 2 and 6, 4 and 12, 5 and 15, &c. and $a e a, b e b, d e d, \&c.$ in discontinued or interrupted Proportion.

Thus having rightly understood what we have said in this 33 and 31 Definition, there will follow these Corollarys as to many Axioms.

II. That equal Quantities have the same proportion to the same

same Quantity (α) and the same has the like to equal Quantities.

III. But a greater quantity has a greater Reason to the same (β) than a less, and the same has a greater proportion to a less Quantity than to a greater.

IV. On the contrary, those that have the (γ) same proportion to the same quantity, and that likewise the same to them are equal.

V. But that which bears a (δ) greater proportion to the same is greater; but that to which the same bears a greater proportion is less.

VI. Proportions equal to one third (ϵ) are also equal among themselves, &c.

DEFINITION XXXIV.

Here remain two things to be taken notice of; First that If any whole (quantity) be so divided into two equal parts (α) that the whole, the greater part and

(α) *Eucl. lib. Prop. 7.* the less are in a continual proportion; the (whole) is said to be cut in extreme and mean

(β) *prop. 8.* Reason. 2. In a continual Series of that kind

(γ) *prop. 9.* Proportionals (e. g. 2. 4. 8. 16. 32, &c. or a , a^2 , a^3 , a^4 , &c.) the Reason of the first Term

(δ) *prop. 10* e^2a , e^3a , e^4a , &c.) the Reason of the first Term

(ϵ) 16. to the third (β) (2 to 8, or a to e^2a) is particularly called Duplicate, and to the 4th (16 to

or e^3a) Triplicate, &c. of that Reason which the same first Term

has to its second, or any other antecedent of that Series to its

Consequent: But generally these Duplicate and Triplicate Reasons, &c. as others also of the first Term to the third or fourth

of Proportions continually cohering together, (whether they

are the same as in the foregoing Examples, or different as in

these, 2, 4, 6, 18, or a , ea , eia , $eioa$, &c. viz. if the name

of the first Reason be e , of the second i , of the third o , &c.) I say, the Reasons of the first

(α) *Eucl. Definit. 3. lib. 6* Term (2 or a) to the third (6 or eia)

(β) *Eucl. Definit. 10. l. 5.* to the 4th (18 or $eioa$) are said to be compounded of the continual intermediate Reasons.

Now from our general Example, what Euclid says, is manifest,

CONSECTARY I.

THAT the denomination of a compounded Reason arises from the Multiplication of the denominations of the given Simple (α) Reasons; as the denomination of the reason compounded of both (*viz.* a to eia) is produced by multiplying the denomination of the first Reason e by the denomination of the second Reason i , and the denomination of the Reason compounded of the three (*viz.* a to $eioa$) is produced by the denomination of the first Reason e , multiplied by the denomination of the second Reason i ; and the Product of these by the denomination of the third Reason o , &c.

CONSECTARY II.

SO that it is very easie after this way, having never so many Reasons given, whether continued (as 2 to 3, 3 to 6, or a , ea , eia ,) or interrupted or discrete (as 2 to 3, and 5 to 10, or a to ea , and b to ib) to express their compounded Reason: In the first case it easily obtain'd by the bare omission of the intermediate Term or Terms (2 to 6, or a to eia ;) and in the other by multiplying first of all the Names of the compounding Reasons among themselves ($1\frac{1}{2}$ and 2, e and i ;) and by the Product (3 or ei) as the name of the Reason compounding the first Term (2 or a) that you may have the other 6 or eia) or (if any one had rather do so in this latter case) by turning the discrete or interrupted Reasons into continued ones, by making as 5 to 10 in the second Reason, so is the Consequent of the first 3 to 6, or as b (α) *Eucl. 1.* to ib , so ea to eia ,) and then by re- 6. *Def. 5.* ferring the first 2 to the third 6, or the first a to the third eia , &c. In a word therefore, any Duplicate Reason may be appositely expressed by a to e^2a , and Triplicate by a to e^3a , the one immediately discernible by a double, the other by a triple Multiplication into itself; as you may also commodiously, and denote others compounded, *e. g.* of 2 by a to eia , of 3 by a to $eioa$, &c.

SCHOLIUM.

WE will here advertise the Reader, that tho the Names duplicate & triplicate Reasons, &c. are chiefly appropriate to Geometrical Proportionality, yet the Moderns have also accommodated them to Arithmetical also; as *e. g.* That *Arithmetical Progression* is called *Duplicate*, whose Terms are the Squares of Numbers Arithmetically Proportional (*e. g.* 1, 4, 9, 16, 25, &c.) and *Triplicate*, whose Terms are Cubes, (&c. as 1, 8, 27, 64, &c.

DEFINITION XXXV.

AND now at length we may understand what Magnitudes Geometers particularly call *like*, or *similar*. Whereas in a General one number may be said to be like another, one right Line to another, one obtuse Angle to another, a Triangle to a Triangle, and the like; but an Acute Angle is not like an Obtuse one, nor a Triangle like a Parallelogram, or a right Line like a Curve one; or a Square like an Oblong, &c. Yet among those Figures which may after that rate in general be said to be like, there is notwithstanding a great deal of dissimilitude; therefore in a strict Sense we call only those Right Lined Figures *similar* or *like* (*a*) which have each of their Angles respectively equal to each of the other (as A and A) B and B C and C, &c. *Fig. 48.*) and the Sides about those equal Angles Proportional, *viz.* as BA to AC, so BA to AC, &c. (and among Solid Figures those are said to be *Similar*, each of whose Planes are respectively Similar one to the other, and equal in number on both sides; as, *e. g.* the Plane AC is similar to the Plane AC, and CG to CG, &c. and six in number on both sides.

Book I.

Section II.

Containing several Propositions demonstrated from the foregoing Foundations.

CHAP. I.

Of the Composition and Division of Quantities.

Proposition I.

THE Sum and Difference of two unequal Quantities added together, make double of the greatest.

Demonstration.

Suppose a be the greatest, b the least, then will their Sum

be $a + b$
And their Difference $a - b$

Their Sum $2a$, by *Confectary* 1. *Definition*
27, Q. E. D.

CONSECTARY.

HENCE by a bare Subsumption (α) you have the truth of *Consect.* 1. *Definit.* 8. that 2 unequal contiguous Angles on the same Right Line, ACD and ACE (*Fig.* 49.) *i. e.* if we call the Right Angle BCD or BCE (α) and the difference between the one and the other (b) $a + b$ and $a - b$, make $2a$, *i. e.* are equal to 2 right ones.

(α) *Eucl. lib.*
6. *Definit.* 1.
(β) *lib.* 11.
Def. 9.
(α) *Eucl.* 13.
1. 11

Proposition II.

IF the Difference of two unequal Quantities be subtracted from their Sum, the Remainder will be double of the least.

Demonstration.

If from the Aggregate or Sum
You subtract the Difference

$$\begin{array}{r} a + b \\ a - b \\ \hline \end{array}$$

The Remainder will be $0 + 2b$ by Con-
sistency 2. Definition 27. Q. E. D.

Proposition III.

BUT if the Sum or Aggregate be subtracted from the Difference, the remainder is so much less than nothing, as is the double of the last Quantity.

Demonstration.

For if from the Difference
You subtract the Sum or Aggregate

$$\begin{array}{r} a - b \\ a + b \\ \hline \end{array}$$

The Remainder will be $0 - 2b$, by Con-
sistency 3 of the aforesaid Definition. Q. E. D.

Proposition IV.

IF a Positive Quantity be multiplied by a Negative one, or contrariwise, the Product will be a Negative Quantity.

Exposition.

If $a - b$ is to be multiplied by c ; it is certain, that a multiplied by c , makes ac a Positive Quantity, by Consist. 1. Definir. 28. Moreover b by the same c (a Negative by a Positive) will make $-bc$; and so the whole Product of $a - b$ by $+c$, will be $ac - bc$.

Demon-

Demonstration.

Suppose $a - b = e$; therefore ec will be $=$ to the Product of $a - b$ by c : and since $a - b$ is $= e$ by the Hypoth. adding on both sides b , you'll have $a = e + b$. by *Schol. Definit. 26.* and multiplying both sides by c , $ac = ec + bc$, by *Consect. 2. Definit. 28.* and by further subtracting from each side bc , you'll have $ac - bc = ec$, that is, to the Product of $a - b$ by c . Q. E. D.

CONSECTARY.

Since $ac - bc$ is the Product of $a - b$ by c , it is manifest also, that if $ac - bc$ be divided by c , you'll have $a - b$ for the Quotient; and so always a Positive Quantity (as ac) divided by a Positive one, c , will give a Positive Quotient; but a Negative Quantity $-bc$ divided by a Positive one, will give a Negative Quotient.

Proposition V.

IF a Negative Quantity be multiplied by a Negative one, the Product will be Positive.

Exposition.

Suppose $a - b$ is to be multiplied by $-c$; it is certain, that a multiplied by $-c$ will give the Negative Quantity $-ac$, by *Prop. 4.* but $-b$ multiplied by the same $-c$ will produce $+bc$, and so the whole Product will be $-ac + bc$.

A Demonstration like the former.

Suppose $a - b = e$, then will $-ec =$ the Product of $a - b$ by $-c$: and since $a - b$ is $= e$, adding b on both sides you'll have $a = e + b$, by *Schol. Definit. 26.* and multiplying both sides by $-c$, you'll have $ac = -ec - bc$, by *Prop. 4.* and *Consect. 2. Definit. 28.* and by adding bc on both sides, you'll have

$-ac$

$-ac + bc = -ec$, i. e. to the Product of $a - b$ by $-c$
Q. E. D.

CONSECTARYS.

I. **S**ince therefore $a - c + bc$ arises from $a - b$ by $-c$ it is manifest, that if $-ac + bc$ be divided again by $-c$, you will again have $a - b$, and consequently a Negative Quantity divided by Negative, will give a Positive Quotient; but a Positive Quantity $+bc$ divided by a Negative one, will give a negative Quotient $-b$.

II. We have therefore the Foundation and Demonstration of the Rules of Specious Computation, in the multiplication and division of Compounded Quantities, viz. that the same Signs multiplied together (as $+$ by $+$ or $-$ by $-$) give $+$ but different (as $+$ by $-$ or $-$ by $+$) give the Sign $-$ Which Rules the following Examples will Illustrate, as also several other we shall meet with in the following Chapter.

Multiplication.

$$\begin{array}{r} a + b \\ a - b \\ \hline aa + ab \\ - ab - bb \\ \hline aa - bb \end{array}$$

$$\begin{array}{r} a - b \\ c - d \\ \hline ac - cb \\ - ad + bd \\ \hline ac - cb - ad + bd \end{array}$$

$$\begin{array}{r} 3d - 4e - 2f \\ 5d - g \\ \hline 15dd - 20de - 10df \\ - 3dg + 4ge - 2gf \\ \hline 15dd - 20de + 10df - 3dg + 4ge - 2g \end{array}$$

Division.

$$\text{by } \begin{array}{r} aa - bb \\ a + b \end{array} (a - b) \mid \text{by } \begin{array}{r} ac - ad - bc + bd \\ e + d \\ e - d \end{array} (a - b)$$

C A A P. II.

Of the Powers of QUANTITIES.

Containing (after a compendious Way) most part of the 2d Book of *Euclid*; and the Appendix of *Clavius* to *Lib. 9. Prop. 14.*

Proposition VI.

IF any whole Quantity be divided into two parts (α) the Rectangle contained under the whole, and one of its parts, is equal to the Square of the same part, and the Rectangle contain'd under both the parts.

(α) *Eucl. lib. 2. prop. 3. A. C. also the third.*

Demonstration.

Let $a + b$ represent the whole
 b one part of it, or

$a + b$
 a the other.

$ab + bb$ the Rectangle,
 (See Fig. 50.)

$aa + ab$ the Rectangle.
 Q. E. D.

Proposition VII.

IF a whole Quantity be divided into two parts (β) the Square of the whole is equal to the Squares of both those parts and 2 Rectangles contained under them.

(β) *Eucl. Prop. 4. lib. 2.*

Demonstration.

This is evident from the preceding, and may moreover thus appear further.

Let

Let the Parts be a and b , then will the whole be $a + b$
 Which if you multiply by it self $a + b$

$$\begin{array}{r} a + b \\ a + b \\ \hline aa + ab \\ ab + bb \end{array}$$

You have the Square $aa + 2ab + bb$
 (See Fig. 51. N. 1.) Q. E. D.

CONSECTARYS.

I. **H**ence you have the Original Rule for Extracting of Square Roots, as we have shewn after *Definition* 30. and here have further Illustrated in *Scheme* N^o 2.

II. Hence it naturally follows, that the Square of double any Side is Quadruple of the Square of that Side taken singly.

III. Hence also you have the addition of surd Numbers, or in general of surd Quantities, by help of the following Rule (supposing in the mean while their Multiplication :) Suppose these 2 Surds $\sqrt{8}$ and $\sqrt{18}$, or more generally $\sqrt{75aa}$ and $\sqrt{27aa}$, are to be added together ; first add their Squares 8 and 18, &c. then double their Rectangle ($\sqrt{144}$) that is, multiply it by the $\sqrt{4}$, and then the double of this $\sqrt{576}$, i. e. having extracted the Square Root, (24) and added it to the Sum of the first Squares (26) the Root of the whole Summ (50) viz. $\sqrt{50}$, is the Sum of the two surd Quantities first proposed.

SCHOLIUM.

BUT if it happens that the Root of the double Product cannot be expressed by a Rational Number (as, when the proposed Quantities are Surds, as $\sqrt{3}$ and $\sqrt{7}$, to whose Squares $3 + 7$, i. e. 10, you must add the double Product of $\sqrt{7}$ by $\sqrt{3}$, i. e. $\sqrt{84}$, which cannot be expressed by a Rational Number) then that double Product must be joined under a Surd Form, or Radical Sign, to the Sum of the Squares (thus, viz. $10 + \sqrt{84}$) and to this whole Aggregate prefix another Radical Sign, thus, $\sqrt{10 + \sqrt{84}}$; or also you may only simply join the Surd Quantities proposed by the Sign $+$ thus, $\sqrt{3} + \sqrt{7}$. Here also you may note, that the two Surd Quantities proposed

in the first case of *Consectary* 2. are called *Communicants*; in the other case of this *Scholium*, *Non-Communicants*: For in this case each quantity under the Radical Sign may be divided by some Square, and have the same Quotient (*e. g.* 8 and 18, may be divided the first by 4, the other by 9, and the Quotient of both will be 2; likewise 75aa and 27aa may be divided, the one by 25aa, the other by 9aa, the Quotient of both being 3; and then if the Quotient on both sides be left under the Radical Sign, and the Root of the dividing Square set before it, the same quantities will be rightly expressed under this form: $2\sqrt{2}$ and $3\sqrt{2}$, also $5a\sqrt{3}$ and $3a\sqrt{3}$; and then the addition is easie, *viz.* only collecting or adding together the Quantities prefixt to the Radical Sign; so that the Sums will be of the one $5\sqrt{2}$ and of the other $8a\sqrt{3}$, which are indeed the same we have shewn in *Consect.* 2. For if contrarywise we square the Quantities that stand without, or are prefixt to the Radical Sign, and then set those Squares (25 and 64aa) under the Radical Sign, multiplying by the Number prefixt to it, you'll have for the one $\sqrt{50}$, for the other $\sqrt{192aa}$ (*Consect.* after *Schol. Prop.* 22.)

Proposition VIII.

IF any whole Quantity (*viz.* Line or Number) be divided (a) into two equal parts, and two unequal ones, the Rectangle of the unequal ones, together with the Square of (the intermediate part or) the difference of the equal part from the unequal one, is equal the Square of the half.

(a) *Eucl. 3^o Clav. 5.*

An Universal Demonstration.

Suppose the parts to be a and a , and the whole $2a$; let one of the unequal Parts be b , the other will be $2a-b$, and the difference between the equal and unequal part $a-b$.

The

$$\begin{array}{r} \text{The equal ones } 2a-b \\ +b \\ \hline \text{Rectangle } 2ab-bb \end{array}$$

$$\begin{array}{r} \text{Difference } a-b \\ a-b \end{array}$$

$$\begin{array}{r} aa-ab \\ -ab+bb \end{array}$$

$$aa-2ab+bb \square$$

The Sum will be aa (the other parts destroying one another)
Q. E. D. (Vid. Fig. 52.)

Proposition IX.

IF to any whole Quantity divided into two equal parts (a) you add another Quantity of the same kind, the Rectangle or Product made of the whole and the part added, multiplied by that part added, together with the square of the half, will be equal to the Square of the Quantity compounded of that half, and the part added.

(a) Eucl. &
Clav. 6.

Demonstration.

Let the whole be called $2a$, the part added b , then the quantity compounded of the whole and the part added will be $2a+b$; and that compounded of the half and the part added $a+b$.

The Quantity compounded of the whole, and the part added, is, $2a+b$ the half a Comp. $a+b$
Multip. by the part added b a $a+b$

$$\begin{array}{r} aa+ab \\ ab+bb \end{array}$$

$$2ab+bb \square \text{ of the half } aa = \square aa+2ab+bb$$

(Vid. Fig. 53.) Q. E. D.

Proposition X.

IF a Quantity be divided any how into (b) two parts, the Square of the whole, together with that of one of its parts, is equal to two Rectangles contained under the whole and the first part, together with the Square of the other part.

(Vid. Fig. 54. N^o 1.)

Q.E.D.

CONSECTARY.

Hence you have the Subtraction of Surd Numbers, or more generally of Surd Quantities, by help of the following Rule.

Add the Squares of the given Roots according to Consect. 3. Prop. 7. and from their Sum subtract the double Rectangle of their Roots; the Root of the Remainder will be the difference sought of the given Quantities.

As, if the $\sqrt{8}$ (BC) is to be subtracted from $\sqrt{50}$ AC (Fig. 54, N^o 1.) you must add 50, i. e. the whole Square AD) and 8, (i. e. the other Square superadded DE,) and the Sum will be 58, equal to the two Rectangles AF and FE + □ GH, by this Prop. I find therefore those two Rectangles by multiplying $\sqrt{50}$ by $\sqrt{8}$, and then the Product $\sqrt{400}$ by 2 or $\sqrt{4}$, thereby to obtain the double Rectangle $\sqrt{1600}$, i. e. (having actually Extracted the Root) 40. This double Rectangle therefore or 40, being subtracted out of the superiour Sum, the remainder 18 will be the □GH, and so its Root (viz. $\sqrt{18}$) gives the required Difference between the given Surd Quantities.

SCHOLIION.

BUT this Subtraction may be performed yet a shorter way, if each quantity under its Radical can be divided by some square,

square, so that the same Quotient may come out on both sides that is, if the Surd Quantities are *Communicants*, as e. g. $\sqrt{50}$ (the number 50 being divided by 25) is equal to $5\sqrt{2}$ and $\sqrt{8}$ to $2\sqrt{2}$; for then the numbers prefix to the Radical Signs being subtracted from one another (*viz.* $2\sqrt{2}$ from $5\sqrt{2}$) you have immediately the remainder or difference $3\sqrt{2}$, i. e. $\sqrt{18}$. But if the proposed Quantities are not *Communicants* (as if $\sqrt{3}$ is to be subtracted from $\sqrt{7}$) the remainder may be briefly expressed by means of the Sign — thus, $\sqrt{7} - \sqrt{3}$, or according to the foregoing *Confectary*, thus, $\sqrt{10} - \sqrt{84}$.

Proposition XI:

IF any Quantity be divided into two parts, (a) the Quadrangle contained under the whole and one of its parts, together with the Square of its other parts, will be equal to the Square of the Quantity compounded of the whole and the other part.

Demonstration.

Suppose $a + b$ the whole.
 b one part.

$ab + bb$ the Rectangle of these two.
 mult. by 4

$4ab + 4bb$ the Quadruple Rectangle.
 Add aa the Square of the other part.

Sum $aa + 4ab + bb$

The Quantity compounded of the whole and the first part

$$\begin{array}{r} a + 2b \\ a + 2b \end{array}$$

$$\begin{array}{r} aa + 2ba \\ 2ba + 4bb \end{array}$$

(a) Eucl. 8.
 Clav. prop. 8.

Square of the Compound Quantity
 (Vid. Fig. 55.)

$$aa + 4ba + 4bb$$

Proposition

Proposition XII.

IF any Quantity be divided into two equal parts (β) and into two other unequal ones, the Squares of the unequal parts taken together will be double the Square of half the quantity, and the Square of the difference, (β) *Eucl. & viz. of the equal and unequal part, taken together. Clav. prop. 9.*

Demonstration.

Suppose the equal parts to be a and a , the difference (b) the greater of the unequal Parts to be $a+b$, the less $a-b$.

<p>The greater part $a+b$</p> <hr style="width: 100%;"/> <p style="text-align: center;">$a+b$</p> <hr style="width: 100%;"/> <p style="text-align: center;">$\square aa + 2ab + bb$</p>	<p>The less $a-b$</p> <hr style="width: 100%;"/> <p style="text-align: center;">$a-b$</p> <hr style="width: 100%;"/> <p style="text-align: center;">$\square aa - 2ab + bb$</p>	<table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="width: 50%; text-align: center;">Half</td> <td style="width: 50%; text-align: center;">Difference</td> </tr> <tr> <td style="text-align: center;">a</td> <td style="text-align: center;">b</td> </tr> <tr> <td style="text-align: center;">a</td> <td style="text-align: center;">b</td> </tr> <tr> <td style="text-align: center;">$\square aa$</td> <td style="text-align: center;">$\square bb$</td> </tr> <tr> <td colspan="2" style="text-align: center;"> <hr style="width: 100%;"/> <p>Sum $aa + bb$</p> </td> </tr> </table>	Half	Difference	a	b	a	b	$\square aa$	$\square bb$	<hr style="width: 100%;"/> <p>Sum $aa + bb$</p>

<p>Sum of these $2aa + 2abb$</p>												

Q. E. D.

(Vid. Fig. 56.)

Proposition XIII.

IF to any whole Quantity (α) divided into two equal parts there be added another Quantity of the same kind, the Square of the Quantity compounded of the whole, and the quantity added, together with the square of the quantity added, will be double the square of the half the quantity, and the square of the Sum of the half and the part added taken together. (α) *Eucl. & Clav. x.*

Demonstration.

Suppose the whole to be $2a$, the half parts a and a , the quantity added b ; then the quantity compounded of the whole and the quantity added, will be $2a+b$, and that of the half and the quantity added $a+b$.

C H A P. III.

Of Progression, or Arithmetical Proportionals.

Proposition XIV.

IF there are 3 Quantities in continued Progression, or Arithmetical continued Proportion, the Sum of the Extremes is double of the middle Term.

Demonstration.

Such are e.g. $a, a+x, a+2x$ ascending,
or $a, a-x, a-2x$ descending.

By Definition 32. the Sum of the Extremes in the first $2a+2x$, in the latter $2a-2x$; in both manifestly double the middle Term Q.E.D.

Proposition XV.

IF there are 4 of these Continued Proportionals, the Sum of the Extreme Terms is equal to the Sum of the middle Terms.

Demon

Demonstration.

Such are e. g. $a, a+x, a+2x, a+3x$, &c. ascending, or $a, a-x, a-2x, a-3x$, &c descending; in the one the Sum of the Extremes is $2a+3x$, in the other $2a-3x$; and also of the means $2a+3x$ and $2a-3x$ Q. E D.

Proposition XVI.

IF there are never so many of these continued Proportionals, the Sum of the Extremes is always equal to the Sum of any 2 other of them, equally remote from the Extremes, or also double of the middle Term, if the number of the Terms is odd.

Demonstration.

Suppose $a, a+x, a+2x, a+3x, a+4x, a+5x, a+6x$, &c. or $a, a-x, a-2x, a-3x, a-4x, a-5x, a-6x$, and the Sum of the Extremes, as also of any 2 equally remote from the Extremes, and the double of the middle Term is in the first Series $2a+6x$, in the latter $2a-6x$, &c. Q.E.D.

SCHOLIUM I.

NOR can we doubt but that this will always be so, how far soever the Progression be continued; if you consider that the last Term contains in it self the first, and moreover the difference so many times taken, as is the number of Terms excepting one, but that the first has no difference added to it; and therefore tho the last since one contains one difference less than the last; the second on the contrary has one more than the first, and consequently the Sum of the one will necessarily be equal to the Sum of the other; and in like manner the last except two, contains two Differences less than the last; but, on the contrary, the third exceeds the first by a double Difference, the double Difference being added to it, &c. as is obvious to the Eye in our first universal Example. Hence you have these

CONSECTARYS.

I. **Y**OU may obtain the Sum of any Terms in Arithmetical Proportion, if the Sum of the Extremes be multiplied by half the number of Terms, or (which is the same thing) half the Sum by the number of Terms,

II. To obtain therefore the Sum of 600, or never so many such Terms, you need only have the Extremes and the number of Terms: So that you have a very compendious Way of proceeding in Questions that are solvable by these Progressions, if, having the first Term and Difference of the Progression given, you can obtain the last, neglecting the intermediate ones.

III. But you may obtain the last Term, by Multiplying the given Difference by the given Number of Terms lessened by Unity, and then adding the first Term to the Product; as is evident from the preceding *Scholium*.

IV. Hence we may easily deduce this Theorem, that the Sum of any Arithmetical Progression beginning from 0, is subduple of the Sum of so many Terms, equal to the greatest, as is the number of Terms of that Progression. For if the first Term is 0 and the last x , and the given number of Terms a , the Sum of the Progression will be $\frac{1}{2} a x$, by *Consect.* 1. but the Sum of so many Terms equal to the greatest, ax . Q.E.D.

SCHOLIUM II.

NOW if any one would be satisfied of the truth of this last *Consect.* without the literal or specious Notes, let him consider, that if the first Term be supposed to be 0, the last (whatever it is) will be the sum of the Extremes. The last therefore multiplied by half the number of Terms, gives the Sum of the Progression, by *Consect.* 1. and the same last Term multiplied by the whole number of Terms, gives the Sum of so many Terms equal to the greatest. But that this must needs be double of the precedent 'tis evident, because any Multiplicand being multiplied by a double multiplier, must needs give a double Product. Now as this Consectary will be of singular Use to us hereafter for Demonstrating several Propositions, so the three former are the very same Practical Rules of Arithmetick, which are commonly made

use of in Arithmetical Progreffions; for the Illustration whereof
Swenterus gives us several Ingenious Examples in his *Delic.* part
 I. Quest. 70. &c.

CHAP. IV.

Of Geometrical Proportion in General.

Proposition XVII.

IF there are three Quantities continually (a) Proportional,
 the Rectangle of the Extremes, is equal to the Square of
 the mean Term.

Demonstration.

Such are e. g.	$a, ea, e^2a,$	The mean Term,	ea
The Extremes	e^2a		ea
	a		
Rectangle	e^2a^2	Square	e^2a^2 Q.E.D.

SCHOLIUM.

Moreover if three Quantities on each side are in the same
 Continual Proportion, as

the Rectangles of the Extremes made Cross-ways, are equal to the Rectangle of the mean Term ; being every way $e^2 ab$.

Whence by the way may appear that Proposition of *Archimedes* (β) That the Surface of a Right Cone is equal to the Circle, whose Radius is a mean Proportional between the Side of that Cone and the Semidiameter of the Base. For suppose EF to be a mean Pro-

(α) *Euc.* 171. proportional between the side of the Cone BC (Fig. 6 & 201. 7. 57.) and the Semidiameter of the Base CD

(β) *lib.* 1. de since an equal number of Peripherys answer to
Sphær. & Cyl. an equal number of Radii in the same Proportion;
Prop. 14. half the Product of the first Line BC into the last Periphery, $\frac{1}{2} e^2 a b$ (that is, by *Consect.*

4. *Definit.* 18. the Surface of the given Cone) will be equal to half Product of the mean Line into the mean Periphery, $\frac{1}{2} e^2 ab$ (i. e. by *Consect.* 2. *Definit.* 15.) to the Area of the Circle of the mean Proportional EF. Q. E. D.

The same Proposition of *Archimedes* may also be Demonstrated after this Way : If the side of the Cone BC be called b , and the Semidiameter of the Base a so that the Periphery may, by *Consect.* 1. *Definit.* 31. be $2ea$, and so the Surface of the Cone by *Consect.* 4. *Definit.* 18. eab the \sqrt{ab} will be a mean proportional between b and a , by this 17th Proposition ; which being taken for Radius, the whole Diameter will be $\sqrt{2ab}$, and the Periphery $2e\sqrt{ab}$; therefore by *Consect.* 2. *Definit.* 15. half the Radius $\frac{1}{2} \sqrt{ab}$ multiplied by the Periphery (since \sqrt{ab} multiplied, by \sqrt{ab} necessarily produces ab) will give you the Area of the Circle by that mean (a) Proportional, equal to the Surface of the given Cone, which before was expressed in the same Terms. Q. E. D.

Hence also naturally flows this other Proposition, That the Surface of the Cone ($\frac{1}{2} e^2 ab$) is to its Base ($\frac{1}{2} ab$) as the Side of the Cone ($e^2 b$) is to the Radius of the Base b , as may appear from the Terms.

Proposition XVIII.

(α) *lib.* 1. de
Sphær. & Cyl.
prop. 15.

(β) *Euc.* 16
1.6 & 19. 7.

IF (β) 4 Quantities are Proportional, either continuedly or discretely, the Product of the Extremes is equal to the Product of the Means.

Demonstr

Demonstration.

Suppose one Continual Proportional, a, ea, e^2a, e^3a .

Extremes e^3a | Means e^2a
 a | ea

Prod. $e^3aa = \text{Prod. } e^3aa$. Q.E.D.

SCHOLIUM.

ON this Theorem is founded the *Rule of Three* in Arithmetick; so called because having 3 Numbers, (2. 5. 8.) it finds an unknown fourth Proportional. For altho this fourth be, as we have said, unknown, yet its Product by 2 is known, because the same with the Product of the Means, 5 and 8. Wherefore the Rule directs to multiply the third by the second, that you may thereby obtain the Product of the Extremes: which divided by one of the Extremes, viz. the first, necessarily gives the other, i. e. the fourth sought.

Proposition XIX.

IF 2 Products (on the other side) arising from the Multiplication of 2 Quantities, are equal, those 4 Quantities will be at least directly Proportional.

Demonstration.

Suppose $e b a$ be the equal Product of the Extremes, and $e a b$ of the Means; the Extremes will either be eb and a , or e and ba , or b and ea , as also the Means. But what way soever either is taken, there can be no other Disposition or placing of them, than one of the following.

I $eb \quad eb \quad a \quad a$
 $\text{---} \quad ee \quad ab$
 $\text{---} \quad ea \quad b; \text{ or inversly.}$
 $\text{---} \quad a \quad eb$
 $\text{---} \quad ab \quad e$

F 4

	—	b	ea	
2	e	e	ba	ba
	—	eb	a	
	—	ea	b	or inverfly.
	—	ba	e	
	—	a	eb	
	—	b	ea	
3	b	b	ea	ea
	—	a	eb	
	—	ba	e	or inverfly.
	—	ea	b	
	—	eb	a	
	—	e	ba	or inverting the Order of them all

In all these Dispositions there may be immediately seen a Geometrical Proportion, by what we have in *Definition 31* and *33*.

CONSECTARIS.

I. **A**S we have shewn one Sign of Proportionality in the Definition of it, *viz.* That the same Quotient will arise by dividing the Consequents by the Antecedents; so now we have another Sign of it, *viz.* The Equality of the Product of the Extremes and Means.

II. By a bare Subsumption may hence appear the Truth of *Prop. 14. lib. 6. Euclid.* at least partly: Which we shall yet more commodiously shew hereafter.

Proposition XX.

IF there are never so many Continual Proportionals, the Product of the Extremes is equal to the Product of any 2 of the Means that are equally distant from the Extremes, as also to the Square of the mean or middle Term, if the Terms are odd.

Demonstration.

Such are *e. g.* $a, ea, e^2a, e^3a, e^4a, e^5a, e^6a$, &c. and the Product of the Extremes, and of any two Terms equally remote from

them, and the Square of the mean or middle Term, every where e^6aa . Q.E.D.

SCHOLIUM I.

NOR can there be any doubt but this will always be so, how far soever the Progression is continued; if you consider that the last Term always contains the first, so many times multiplied as is the place of that Term in the rank of Terms, excepting one. Altho therefore the last Term but one is in one degree of its Reason less than the last, the second on the contrary, is in one more than the first, therefore the Product of the one will necessarily be equal to the Product of the other. Thus also the last Term being in one Degree of Proportion lower than the first, the first being to be multiplied into that, exceeds the first by one Degree of the Proportion, &c. as may be seen in our Universal Example. Hence you have the following

CONSECTARIES.

HAVING some of the Terms given in a Continual Proportion (e.g. suppose 10) you may easily find any other that shall be required (e.g. the 17th) as the last; If the 2 Terms given, being equally remote from the first and that required (as are e.g. the eighth and tenth) be multiplied by one another, and this Product, like that also of the Extremes, be divided by the first.

II. But this may be performed easier, if you moreover take in this Observation, That if, e.g. never so many places of proportionals, passing over the the first, be noted or marked by Ordinals or Numbers according to their places (as in this universal Example)

$a, ea, e^2a, e^3a, e^4a, e^5a, e^6a,$

I. II. III. IV. V. VI.

The place of the 7th Term is (e.g.) VI. (and so the place of any other of them being less by Unity than its number is among the Terms) and also composed of the places of any other equally distant from the Extremes, e. g. V. and I. IV. and II. or twice III. &c.

III. Here

III: Here you have the Foundation of the Logarithms, of a Compendious Way of Arithmetick, never enough to be praised. For if, *e.g.* a rank of Numbers from Unity, continually Proportional, be signed or noted with their Ordinals, as we have said, as Logarithms,

I. 2. 4. 8. 16. 32. 64. 128. 256, &c.
I. II. III. IV. V. VI. VII. VIII.

and any two of them (as 8 and 32) are to be multiplied together; add their Logarithms III and V, and their Sum VIII gives you the Logarithm of their Product 256, as the Term equally remote from the 2 given ones and the first, and whose Product with the first (which is Unity) *i.e.* it self will be equal to the Product of the Numbers to be multiplied: And contrariwise, if, *e.g.* 128 is to be divided by 4, subtracting the Logarithm of the first II from the Logarithm of the second VII the remaining Logarithm V points out the number sought 32 so that after this way the Multiplication of Proportionals is by a wonderful Compendium, turned into Addition, and the Division into Subtraction, and Extraction of the Square Root into Bisection or Halving, (for the Logarithm of the Square Number 16 being Bisected, the half II gives the Root sought 4) of the Cube Root into Trisection (for the Logarithm of the Cube 64 being Trisected, the third part gives the Cubic Root sought 4).

SCHOLIUM II.

THAT we may exhibit the whole Reason of this admirable Artifice (which about 35 years ago was found out by the Honourable Lord *John Naper* Baron of *Merchiston* in Scotland and published something difficult, but afterwards render'd much easier and brought to perfection by *Henry Briggs*, the first *Scotian* Professor of Geometry at *Oxford*.) I say that we may exhibit the whole Reason of it in a Synopsis, after an easie way when its use appear'd so very Considerable in the great Numbers in the Tables of Sines and Tangents, nor yet could they be useful without mixing vulgar Numbers with them, especially in the Practical Parts of Geometry, the business was to accommodate

commodat

commodate this Logarithmical Artifice to them both. First therefore that Artists might assign Logarithms to all the common Numbers proceeding from 1 to 1000 and 10000, &c. they first of all pick out those which proceed in continued Geometrical Proportion, and particularly, tho arbitrarily, those which increase in a Decuple Proportion, *e.g.* 1. 10. 100. 1000. 10000, &c.

But now to fit them according to the Foundation of *Consect.* 3. a Series of Ordinals in Arithmetical Progression, we don't only substitute the simple Number 1, 2, 3, &c. but augmented with several Cyphers after them, that so we may also assign their Logarithms in whole Numbers to the intermediate Numbers between 1 and 10, 10 and 100, &c. Wherefore, by this first Supposition, Logarithms in Arithmetical Proportion, answer to those Numbers in Geometrical Proportion, after the way we here see,

	1	10	100
Log.	0000000	10000000	20000000
		1000	10000
		30000000	40000000, &c.

As that they also exhibit certain Characteristical initial Notes, whereby you may see, that all the Logarithms between 1 and 10 begin from 0, the rest between 10 and 100 from 1, the next from 100 to 1000 from 2, &c.

The Logarithms of the Primary Proportional Numbers being thus found, there remain'd the Logarithms of the intermediate Numbers between these to be found: For the making of which, after different ways, several Rules might be given drawn from the Nature of Logarithms, and already shewn in *Consect.* 3. See *Briggs's Arithmetica Logarithmica*, and *Gellibrand's Trigonometria Britannica*; the first whereof, *chap.* 5. and the following, shews at length both ways delivered by *Neper* in his *Appendix*. But the business is done more simply by *A. Vlacq.* in his Tables of Sines &c. whose mind we will yet further explain thus: If you are to find, *e.g.* the Logarithm of the Number 9, between 1 and 10, augmented by as many Cyphers as you added to the Logarithm of 10, or the rest of the Proportionals (*b.e.* between

10000000

10000000 and 100000000) you must find a Geometrical Mean Proportional, *viz.* by multiplying these Numbers together and extracting the Square Root out of the Product, by Prop. 17. Now if this Mean Proportional be less than 9 augmented by as many Cyphers, between it and the former Denary Number you must find a second mean Proportional, then between this and that same a third; and so a fourth, &c. but if it be greater, then you must find a mean Proportional between it and the next less, &c. till at length after several Operations you obtain the number 9999998, approaching near 90000000. Now if between the Logarithm of Unity and Ten (*i. e.* between 0 and 10000000) you take an Arithmetical Mean Proportional (05000000) by Bisecting their Sum by Prop. 14. and then between this and the same Logarithm of Ten, you take another mean, and so a third and a fourth, &c. at length you will obtain that which answers to the last above mentioned, *viz.* 9. See the following Specimen.

A TABLE of the Geometrical Proportionals between 1 and 10, augmented by 7 Cyphers, and of the Arithmetical Proportionals between 0 and 10000000 being the Logarithms corresponding to them.

Geometrical Mean Pro- portionals.		Arithmetical Logar. mean Proportionals
31622777	First,	05000000
56234132	Second,	07500000
74989426	Third,	08750000
86596435	Fourth,	09375000
93057205	Fifth,	09687500
89768698	Sixth,	09531250
91398327	Seventh,	39609375
90579847	Eighth,	09570312
90173360	Ninth,	09550781
89970801	Tenth.	09541015

Which is thus made: In the first Table a Geometrical Mean proportional between 10000 000 and 100 000 000 the first Number of it; then another Mean between that and the same last 100000000, gives the second; and so to the fifth, 93057205. Which, since it is already greater than the Novenary, another Mean between it and the precedent fourth, comes in order a sixth, but sensibly less than the Novenary. Therefore between it and the fifth you will have a seventh Mean yet greater than the Novenary; and between the sixth and seventh, an eighth, somewhat nearer to the Novenary, but yet sensibly equal, but somewhat bigger; moreover between the sixth and eighth you will have a ninth, between the ninth and sixth a tenth gradually approaching nearer the Novenary, but yet somewhat sensibly differing from it. Now if you continue this inquiry of a mean Proportional between this tenth, somewhat too little, and the precedent ninth as somewhat too big, and so onwards, you will at length obtain the Number 8999 9998, only differing two in the last place from the Novenary Number augmented by seven Cyphers, and consequently insensibly from the Novenary it self. But for the Logarithm of this in the second Column, by the same process you are to find Arithmetical Mean Proportionals between every 2 Logarithms answering to every two of the superiour ones, till you find, e. g. the Logarithm of the tenth Number 09541015, and so at length the Logarithm of the last, not sensibly differing from the Novenary, 09542425.

Thus having found, with a great deal of labour, but also with a great deal of advantage to those that make use of them, the Logarithms of some of the numbers between 1 and 10, and 10 and 100, &c. you may find innumerable ones of the other intermediate Numbers with much less labour, viz. by the help of some Rules, which may be thus obtain'd from *Consect.* 3 of the precedent Proposition. *The Sum of the Logarithms of the number Multiplying and the Multiplicand, gives the Logarithm of the Product.* 2. *The Logarithm of the Divisor subtracted from the Logarithm of the Dividend, leaves the Logarithm of the Quotient:* the Logarithm of any number doubled, is the Logarithm of the Square, tripled of the Cube, &c. 4. *The half Logarithm of any number is the Logarithm of the Square Root of that number, the third part of the Logarithm of the Cube Root, &c.* Thus, e. g. if you have found the Logarithm

garithm of the number 9, after the way we have shewn, by the same reason you may find the Logarithm of the number 5 (as before) by finding mean Proportionals between the second and the first number of our Table, and between their Logarithms, &c. and by means of these 2 Logarithms you may obtain several others: First, since 10 divided by 5 gives 2; if the Logarithm of 5 be subtracted from the Logarithm of 10, you'll have the Logarithm of 2, by Rule the second. Secondly, since 10 multiplied by 2 makes 20, and by 9 makes 90, by adding the Logarithms of 10 and 2, and 10 and 9, you'll have the Logarithms of the numbers 20 and 90, by Rule 1. Thirdly, Since 9 is a Square, and its Root 3, half the Logarithm of 9 gives the Logarithm of 3, by Rule 4. since 90 divided by 3 gives 30, the Logarithm of this number may be had by subtracting the Logarithm of 3 from the Logarithm of 90, by Rule the second. Fifthly, 5 and 9 squared make 25 and 81, the Logarithms of 5 and 9 doubled, give the Logarithms of these numbers, by Rule 3. In like manner, sixthly, the Sum of the Logarithms of 2 and 3, or the Difference of the Logarithms of 5 and 30, give the Logarithm of 6, and the Sum of the Logarithms of 3 and 6, or 2 and 9, gives the Logarithm of 18; the Logarithm of 6 doubled, gives the Logarithm of 36, &c. And after this way you may find and reduce to Tables, the Logarithms of Vulgar Numbers from 1 to 100000 (as in the Tables of *Strauch*. p. 182, and the following) or 1000000 (as in the *Chiliads* of *Briggs*.) But as to the manner of deducing the Tables of Sines and Tangents from these Logarithms of Vulgar Numbers, we will shew it in *Schol.* of *Prop.* 55, only hinting this one thing before-hand; that this Artifice of making Logarithms is elegantly set forth by *Pardies* in his *Elements of Geometry*, pt 112. by a certain Curve Line then called the *Logarithmical Line*; by the help whereof he supposes Logarithms may be easily made; and having found those of the numbers between 1000 and 10000, he shews, that all others may be easily had between 1 and 1000. Wherefore we shall Discourse more largely in *Schol. Definit.* 15. lib. 2.

Proposition XXI.

IF the first Term of never so many Continual Proportionals, be subtracted from the last, and the Remainder divided by the name of the Reason or Proportion lessen'd by Unity, the Quotient will be equal to the Sum of all except the last.

Demonstration.

$$e a$$

$$e^2 a$$

$$e^3 a$$

$$e^4 a$$

$$e^5 a$$

The last Term less the first $e^6 a - a$

Divided by the name of the Reason lessen'd by unity.

$$\begin{array}{l} e - 1 \\ e - 1 \\ e - 1 \\ e - 1 \\ e - 1 \\ e - 1 \end{array} \left| \begin{array}{l} * \text{Quote. } e^5 a + e^4 a + e^3 a + \\ e^2 a + e a + a ; \\ \text{And it is evident from the} \\ \text{Operation, that the same} \\ \text{will always happen tho the} \\ \text{number of Terms be con-} \\ \text{tinued never so far.} \end{array} \right.$$

CONSECTARYS.

IW Herefore in adding never so great a Series of Geometrical Proportionals, since it is enough that the first and last Term, and the Name of the Reason be known, by this Prop. and having found at least some of the Terms of the Proportion, any other may be afterwards found, whose place will be compounded of the places of the two Antecedent ones, according to Consect. 2. Prop. 20. viz. by Multiplying the Terms answering to the two above-mentioned places, and dividing the Product by the first Term; thence it will be very easie to add a great Series of Proportionals into one Sum, tho the particular separate Terms remain almost all of them unknown.

SCHOLIUM

SCHOLIUM.

These are the same Practical Arithmetical Rules concerning Geometrical Progressions; for the illustration of which *Swenterus in Delic.* has given us so many pleasant Examples, *1. Prop. 59. and fol.* First of all, that famous Example is of the kind which relates to the Chequer-work'd Table or Board flinging Dice on, with its 64 little Squares, which *Dr. Wallis* has translated out of the Arabick of *Ebn Chalecan*, into Latin in *Oper. Mathem. part. 1. Chap. 31.* for the illustration of which we have heretofore compos'd an Exercitation, and shall here only note these few things: If there are supposed 64 Terms in double Proportion from Unity, and the first of them, not with their local Numbers, are these that follow;

1	2	4	8	16	32	64	128
I	II	III	IV	V	VI	VII	

You may have the Term of the 13th place, 8192, by multiplying together the VIth and VIIth place; and the Term of the XXVIth place, by squaring or multiplying this new Product again by it self, and moreover the Term of the LIIIth place, by multiplying that Product again by itself; and furthermore the Term of the LIXth place, by multiplication of the number last found by the number of the VIIth place, and lastly the Term of the LXIIIth place (*i. e.* the last in the proposed Series) by multiplying this last of all by the number of the IVth place.

II. Moreover you may, by this Art, collect infinite Series of Proportional Terms into one Sum, altho it is impossible to run over all the Terms separately, because infinite. *e. g.* in a continued Series of Fractions, decreasing in a double Proportion $\frac{1}{2}$ $\frac{1}{4}$, $\frac{1}{8}$ $\frac{1}{16}$ $\frac{1}{32}$, &c. *ad infinitum*, if you take them backwards, you may justly reckon a Cypher or 0, for the first Term (for between $\frac{1}{2}$ and 0 there may be an infinite Number of such Terms) and the infinite Sum of these Terms will be precisely equal to Unity; for subtracting the first 0, from the last $\frac{1}{2}$, and the remainder $\frac{1}{2}$ being divided by the name of the Reason lessened by 1, *i. e.* by 1. which divides nothing, the

Quotient

Quotient $\frac{1}{2}$ is the Sum of all the Terms excepting the last, by Prop. 21. and so the last $\frac{1}{2}$ being added, the Sum of all in that Series will be 1. Now if the last is not $\frac{1}{2}$ but 1, the Sum of all will necessarily be 2; if 2 be the last, the Sum of all will be 4; in a word, it will be always double the last Term.

III. And since in this case the Sum of all the precedent Terms is equal to the last Term, the one being subtracted from the other, there will remain nothing, i. e. $\frac{1}{2} - \frac{1}{4} - \frac{1}{8} - \frac{1}{16} - \frac{1}{32}$, &c. in *Infinitem*, is $= 0$, and also $1 - \frac{1}{2} - \frac{1}{4}$, &c. or $2 - 1 - \frac{1}{2} - \frac{1}{4}$, &c. $= 0$.

IV. In like manner the Sum of infinite Fractions decreasing in triple Reason in an infinite Series ($\frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81}$, &c.) will be equal to $\frac{1}{2}$: for if from the last $\frac{1}{3}$ (again in an inverted Order) you subtract the first 0, and the Remainder $\frac{1}{3}$ be divided by the name of the Reason lessened by Unit, i. e. by 2, the Quotient $\frac{1}{6}$ will be the Sum of all the antecedent Terms, and adding to this last $\frac{1}{3}$ or $\frac{2}{6}$ the Sum of all will be $\frac{3}{6}$ or $\frac{1}{2}$.

V. Thus an infinite Series of Fractions decreasing from $\frac{1}{4}$ in a Quadruple Proportion ($\frac{1}{4} + \frac{1}{16} + \frac{1}{64}$, &c.) is equal to $\frac{1}{3}$; for subtracting the first 0 from the last $\frac{1}{4}$, and the remainder $\frac{1}{4}$ being divided by the name of the Proportion, i. e. by 3, you will have $\frac{1}{12}$ the sum of all except the last, and adding also the last $\frac{1}{4}$ or $\frac{3}{12}$, you'll have the whole Sum $\frac{4}{12}$ or $\frac{1}{3}$.

VI. Thus also an infinite Series decreasing from $\frac{1}{5}$ in a Quintuple Proportion ($\frac{1}{5} + \frac{1}{25} + \frac{1}{125}$, &c.) is equal to $\frac{1}{4}$: $\frac{1}{5} + \frac{1}{25} + \frac{1}{125}$, &c. is equal to $\frac{1}{5}$, &c. and so any Series of this kind is equal to a Fraction, whose Denominator is less by an Unit than the Denominator of the last Fraction in that Series.

VII. Generally also, any infinite Series of Fractions decreasing according to the Proportion of the Denominator of the last Term, and having a common Denominator less by an unit than the Denominator of the last Term (e. g. $\frac{2}{3} + \frac{2}{9} + \frac{2}{27}$, &c. or $\frac{3}{4} + \frac{3}{16} + \frac{3}{64}$, &c. or $\frac{4}{5} + \frac{4}{25} + \frac{4}{125}$, &c.) is equal to Unity, after the same way as the Series Consect. 2. which may be comprehended under this kind, and which may be demonstrated in all its particular cases by the same method we have hitherto made use of, or also barely subsumed from Consect. 4, 5, and 6. For since $\frac{1}{3} + \frac{1}{9} + \frac{1}{27}$, &c. is equal to $\frac{1}{2}$; $\frac{2}{3} + \frac{2}{9} + \frac{2}{27}$ will be equal to $\frac{3}{2}$, or 1, and so on the rest.

VIII. Particularly the sum of $\frac{3}{27} + \frac{3}{288} + \frac{3}{1152}$, &c, decreasing in a Quadruple Proportion, is equal to $\frac{1}{18}$; and the sum of $\frac{3}{256} + \frac{3}{1024}$, &c. is equal to $\frac{1}{16}$; and the sum of $\frac{7}{64} + \frac{7}{512} + \frac{7}{4096}$, &c. decreasing in Octuple Proportion, is equal to $\frac{1}{8}$: For subtracting the first Term 0, and dividing the remainder by the name of the Reason less'n'd by 1, i. e. by 3, the Quotient $\frac{1}{72}$ gives the sum of all except the last. This therefore (*viz.* $\frac{3}{72}$) being added, the sum of all will be $\frac{4}{72}$ or $\frac{1}{18}$: In like manner $\frac{7}{64}$ being divided by the name of the Reason less'n'd by Unity, the Quotient will give $\frac{1}{64}$, and adding the last, the sum of all will be $\frac{1}{64} + \frac{1}{64} = \frac{1}{32}$, i. e. $\frac{1}{8}$. So that hence it is evident, that $\frac{1}{18} - \frac{3}{72} - \frac{3}{288} - \frac{3}{1152}$, &c. or $-\frac{1}{18} + \frac{3}{72} + \frac{3}{288} + \frac{3}{1152}$, &c. in Infinitum, will be equal to nothing; also $\frac{1}{8} - \frac{7}{64} - \frac{7}{512} - \frac{7}{4096}$ &c. = 0.

IX. The Sum of a simple Arithmetical Progression (i. e. ascending by the Cardinal Numbers) continued from 1, ad Infinitum, is Simple of the Sum of the same number of Terms, each of which is equal to the greatest; or on the contrary, this latter Sum is double of the former. We might have subsumed this in *Consect. 4. Prop. 16.* for, prefixing a Cypher before Unity, it will be a case of that *Consectary*, the Sum of the Progression remaining still the same. But that this is true, in an infinite Series beginning from Unity (whether in a finite or determinate one, the proportion of the Sum is always less than double, tho it always approaches to it, and comes so much the nearer by how much greater the Series is) we shall now thus Demonstrate: To the Sum of three Terms, 1, 2, 3, i. e. 6, the sum of as many equal in number to the greatest, i. e. 9, has the same Proportion as 3 to 2; but the sum of six Terms, 1, 2, 3, 4, 5, 6, i. e. 21, the sum of as many equal to the greatest, i. e. 36, has the same proportion as 3 to $1 + \frac{3}{4}$, that is, as 3 to $2 - \frac{1}{4}$, the decrease being $\frac{1}{4}$: but to the sum of 12 Terms, which may be found by *Consect. 1. Prop. 16.* = 78, the sum of so many equal to the greatest, *viz.* 144. has the same proportion (dividing both sides by 48) as 3 to $1 + \frac{1}{2} + \frac{1}{8}$ (for 24 make $\frac{1}{2}$, and the remainder $\frac{48}{8}$ is the same as $\frac{1}{8}$) that is, as 3 to $2 - \frac{1}{4}$, the decrement being now $\frac{1}{4}$. Since therefore, by doubling the number of Terms onward, you'll find the decrement to be $\frac{1}{2}$, and so onwards in double Proportion; the sum of an infinite Number of such Terms, in Arithmetical Progression, equal to the greatest.

will be to the sum of the Progression from 1, *ad Infinitum*, as 3 to 2— $\frac{1}{4}$ — $\frac{1}{8}$ — $\frac{1}{16}$, &c. that is, by *Consect.* 2 and 3, as 3 to 2— $\frac{1}{2}$, that is, as 3 to 1 $\frac{1}{2}$, or as 2 to 1. Q.E.D.

X. The Sum of any Duplicate Arithmetical Progression (*i.e.* a Progression of Squares of whole numbers ascending) continued from 1 *ad Infinitum*, is subtriple of the Sum of as many Terms equal to the greatest as is the number of Terms: For any such finite Progression is greater than the subtriple Proportion, but approaches nearer and nearer to it continually, by how much the farther the Series of the Progression is carried on. Thus the Sum of 3 Terms 1, 4, 9=14 is to thrice 9=27 as 1 $\frac{1}{3}$, or 1 $\frac{10}{18}$, or 1+ $\frac{1}{2}$ + $\frac{1}{18}$ to 3 (dividing both sides by 9,) the Sum of six Terms, 1, 4, 9, 16, 25, 36, *viz.* 91. to six times 36, *i.e.* to 216 (dividing both sides by 72) is as 1+ $\frac{1}{4}$ + $\frac{1}{72}$ to 3; and the Sum of 12 Terms 650, to 12 times 144, *i.e.* to 1728 (dividing both sides by 576) is as 1+ $\frac{1}{8}$ + $\frac{1}{288}$ to 3, &c. the Fractions adhering to them thus constantly decreasing, some by their half parts, others by three quarters (for $\frac{1}{8}$ is $\frac{1}{72}$; therefore the first decrement is $\frac{3}{72}$ and $\frac{1}{72}$, is $\frac{4}{288}$; therefore the second decrement is $\frac{3}{288}$, &c.) Wherefore the Sum of the Infinite Progression will be to the Sum of the like number of Terms equal to the greatest, as

$$\begin{array}{r} 1 + \frac{1}{2} + \frac{1}{8} \\ - \frac{1}{4} - \frac{3}{72} \\ - \frac{1}{8} - \frac{3}{288} \\ - \frac{1}{18} \&c. - \frac{3}{1152}, \&c. \end{array}$$

to 3, that is, by *Consect.* 3 and 8, as 1 to 3. Q.E.D.

XI. The Sum of a triplicate Arithmetical Progression (*i.e.* ascending by the Cubes of the Cardinal Numbers) proceeding from 1 thro' 27, 64, &c. *ad Infinitum*, is Subquadruple of the Sum of the like number of Terms equal to the greatest. For the Sum of 4 Terms, 1, 8, 27, 64, *i.e.* 100, to 4 times 64, *i.e.* 256 (dividing both sides by 64) will be found to be as 1+ $\frac{1}{2}$ + $\frac{1}{4}$ to 4; but the Sum of 8 Terms, 1, 8, 27, 64, 125, 216, 343, 582, *i.e.* 1296 to 8 times 512, that is, 4096 (dividing both sides by 1024) will be found to be as 1+ $\frac{1}{4}$ + $\frac{1}{16}$ to 4, &c. The adhering Fractions thus

constantly decreasing, the one by their $\frac{1}{2}$ part, the others by $\frac{1}{4}$ (for $\frac{1}{2}$ is $\frac{4}{8}$, and $\frac{1}{4}$ is $\frac{2}{8}$, &c. Wherefore the Sum of the Infinite Progression will be to the Sum of a like (Infinite) number of Terms, equal to the greatest, as

$$\begin{array}{r} 1 + \frac{1}{2} + \frac{1}{8} \\ - \frac{1}{2} - \frac{1}{4} - \frac{1}{8} \\ - \frac{4}{8}, \text{ \&c. } - \frac{3}{8}, \text{ \&c. to } 4; \end{array}$$

that is, by Consect. 2 and 8, as 1 to 4. Q. E. D.

XII. The Sum of an Infinite Progression, whose greatest Term is a Square Number, the others decreasing according to the odd numbers 1, 3, 5, 7, &c. is in Subsesquialteran Proportion of the Sum of the like number of equal Terms, i. e. as 2 to 3. For the Sum of three such Terms, e. g. 9, 8, 7, i. e. 22 to thrice 9, i. e. 27. is (dividing both sides by 9) $2\frac{2}{9}$, viz. $\frac{20}{9}$ to 3, or $2 + \frac{2}{9}$ to 3. But the Sum of six such Terms, 36, 35, 32, 27, 20, 11, i. e. 161, to six times 36, i. e. 216 (dividing both sides by 72) is as $2 + \frac{1}{4}$ to 3, the adhering Fractions thus always decreasing, some by $\frac{1}{2}$, others by $\frac{3}{4}$, as above in Consect. 10. Wherefore the Sum of the Infinite Progression will be to the Sum of the like number of Terms equal to the greatest, as

$$\begin{array}{r} 2 + \frac{1}{2} - \frac{1}{8} \\ - \frac{1}{4} + \frac{3}{8} \\ - \frac{1}{8} + \frac{3}{8}, \text{ \&c. to } 3, \text{ i. e. by Consect. } 3 \text{ and } 8, \text{ as } 2 \text{ to } 3. \text{ Q. E. D.} \end{array}$$

SCHOLIUM II.

THUS we have, after our method, demonstrated the chief Foundations of the Science or Method, or *Arithmetick* of *Infinities*, first found out by Dr. John Wallis, Savilian Professor of Geometry at Oxford, and afterwards carried further by Desiderius Cluverus, and Ismael Bullialdus. And from these Foundations we will in the following Treatise demonstrate, and that directly and *a priori*, in a few Lines, the chief Propositions of

Geometry

Geometry, which the Antients have spent so much labour, and composed such large Volumes to demonstrate, and that but indirectly neither.

Proposition XXII:

THe Powers of Proportionals whether continuedly or discretely, such as the Squares, Cubes, &c. are also Proportional.

Demonstration.

Continual Proportionals.					Discrete Proportionals.				
	a	ea	e^2a	e^3a		a	ea	b	eb
Squares	aa	e^2a^2	e^4a^2	e^6a^2		a^2	e^2a^2	b^2	e^2b^2
Cubes	a^3	e^3a^3	e^6a^3	e^9a^3		a^3	e^3a^3	b^3	e^3b^3

Q. E. D.

SCHOLIUM.

YOU founded in this Truth, 1. the Reason of the Multiplication and Division of Surd Quantities: For since from the Nature and Definition of Multiplication, it is certain, that 1 is to the Multiplier as the Multiplicand to the Product (for the multiplicand being added as many times to it self as there are Units in the Multiplier, makes the Product) if the $\sqrt{5}$ is to be multiplied by $\sqrt{3}$, then as 1 to the $\sqrt{3}$, so the $\sqrt{5}$ to the Product; and, by the present Proposition, as 1 to 3, so 5 to the \square Product, i. e. to 15. Wherefore the Product is $\sqrt{15}$; and so the Rule for Multiplying Surd Quantities is this: *Multiply the Quantity under the Radical Signs, and prefix a Radical Sign to the Product.* Likewise since it is certain from the Nature of Division, that the Divisor is to the Dividend as 1 to the Quotient (for the Quotient expresses by its Units how many times the Divisor is contained in the Dividend) if the $\sqrt{15}$ is to be divided by $\sqrt{5}$, you'll have $\sqrt{5}$ to the $\sqrt{15}$ as 1 to the Quotient, and, by the present Scholium, 5 to 15, as 1 to the \square of the Quotient, i. e., to 3. Therefore the Quotient is the Root of 3, and so the Rule of dividing Surd Quantities this; viz.

G 3

Divide

(a) Eucl. lib.
6. prop. 22.

Divide the Quantities themselves under the Radical Signs, and prefix the Radical Sign to the Quotient.

II. Hence also flows the usual Reduction in the Arithmetic of Surds, of Surd Quantities to others partly Rational, and on the contrary, of those to the form of Surds, e. g. If you would reduce this mixt Quantity $2a\sqrt{b}$, i. e. $2a$ multiplied by the \sqrt{b} , to the form of a Surd Quantity; which shall all be contained under a Radical Sign; The Square of a Rational Quantity without a Sign $4aa$, if it be put under a Radical Sign, in this form $\sqrt{4aa}$, it equivalent to the Rational Quantity $2a$; but the $\sqrt{4aa}$ being multiplied by \sqrt{b} makes $\sqrt{4aab}$. by N. 1. of this Scholium. Therefore $\sqrt{4aab}$ is also equivalent to the Quantity first proposed $2a\sqrt{b}$. Reciprocally therefore, if this form of a meer Surd Quantity $\sqrt{4aab}$, is to be reduced to one more Simple, which may contain without the Radical Sign whatever is therein Rational, by dividing the Quantity comprehended under the sign $\sqrt{\quad}$ by some Square or Cube, &c. as here by $4aa$, (i. e. $\sqrt{4aab}$ by $\sqrt{4aa}$, i. e. $2a$) the Quotient will be \sqrt{b} , which multiplied by the Divisor $2a$, will rightly express the proposed Quantity under this more simple Form $2a\sqrt{b}$. Which may also serve further to illustrate the Scholia of Prop. 7. and 10.

Proposition XXIII.

IF there are four Quantities Proportional, (a, ea, b, eb) they will be also Proportional,

- | | |
|------------------------|---|
| (α) Eucl. 15, | 1. Inversly. ea to a as eb to b . |
| 16. v. 9 10, | 2. Alternately, (α) a to b as ea to eb . |
| 13, vi. | 3. Compoundedly, (β) $a+ea$ to ea , so $b+eb$ to eb . |
| (β) 18, v. | to eb . |
| (γ) 17, v. | 4. Conversely, $a+ea$ to a as $b+eb$ to b . |
| | 5. Dividedly, (γ) $a-ea$ to a as $b-eb$ to b . |
| | 6. (α) By a Syllepsis, a to ea as $a+b$ to $ea+eb$. |
| | 7. By a Dialeptis, a to ea as $a-b$ to $ea-eb$. |

Which are all manifest, by comparing the Rectangles of the Means and Extremes according to to Prop. 19. and its Consect. 1.

or by dividing any of the Consequents by their Antecedents, according to Def. 31.

Proposition XXIV.

IF in a (β) double Rank of Quantities you have
as a to ea , and also as ea to oa ,
so b to eb , and also so eb to ob ,
then you'll have also by proportion of Equality orderly placed,

as the first a , to the last oa , in the first Series;
so the first b , to the last ob , in the second Series.

Which is manifest from the Terms themselves.

Proposition XXV.

BUT (γ) if they are disorderly plac'd
as oa to ea * as ea to a †
† so eb to ob so ob to eb , * you'll have here
again by proportion of Equality,

as the first oa to the last a , in the first Series;
so the first eb to the last eb , in the second Series.

As is evident from the Rectangles of the Extremes and Means, as also from the very Terms.

(α) Eucl. I.
12. v. 5. 6.
12. vii.

(β) Eucl. 3,
20. 22. lib. v.
14. vii.

(γ) Eucl. 21,
23. lib. v.

Proposition XXVI.

IF (α) as the whole ea to the whole a , so the part eb to the part b ; then also will

the Remainder	Remainder	Whole	Whole
$ea - eb$ to the	$a - b$,	as the	ea to the a .

This is evident from the Rectangle of the Extremes and Means, both which are $caa - eab$. Q.E.D.

Proposition XXVII.

RECTANGLES or Products having one common Efficient or Side, are one to another as the other Efficient or Sides.

G 4

Demon-

Demonstration.

Suppose the Products to be ab and ac , having the common Efficient a ; I say they are

as b to c , so ab to ac .

Which is evident at first sight, by comparing the Products of the Extremes and Means, and also fully shews, that other way of proving Proportionality, whereby by dividing the Consequents by their Antecedents, the identity or sameness of the Quotients are wont to be demonstrated.

SCHOLIUM I.

I. **T**He Reduction of Fractions either to more compounded or more simple ones is founded on this Theorem; on the one hand by multiplying, on the other by dividing, by the same quantity, both the Numerator and the Denominator, as, $\frac{a}{b}$ and $\frac{ac}{ab}$ and $\frac{cac}{cab}$, $\frac{1}{3}$, $\frac{2}{9}$, $\frac{4}{2}$, &c. are in reality the same Fractions. And

II. The Reduction of Fractions to the same Denomination,

(α) *Eucl. 5* as if $\frac{b}{c}$ and $\frac{a}{d}$ are to be changed into two others that shall have same Denominator; this is to be done by multiplying the Denominators together for a new Denominator, and each Numerator by the Denominator of the other for a new Numerator, and you'll have for the two Fractions above $\frac{bd}{cd}$ and $\frac{ac}{cd}$

(β) *Besides several other Prop. see also the 17 & 18 lib. vii.*

SCHOLIUM II.

WE will here for a conclusion of Proportionals, shew the way of cutting or dividing any Quantity in *Mean and Extreme Reason*, viz. if for the greater Part you put x , the less will

will be $a-x$; and so by Hypoth. these three, a , x and $a-x$, will be proportional, by Def. 34. Therefore by Prop. 17. the Product of the Extremes $aa-ax$ = to the Square of the Mean xx , and (adding on both sides ax) $aa=xx+ax$; and moreover adding on both sides $\frac{1}{4}aa$, you'll have $\frac{5}{4}aa=xx+ax+\frac{1}{4}aa$. Now this last Quantity, since it is an exact Square, whose Root is $x+\frac{1}{2}a$, you'll have $\sqrt{\frac{5}{4}aa}=x+\frac{1}{2}a$, and (subtracting from both sides $\frac{1}{2}a$) $\sqrt{\frac{5}{4}aa}-\frac{1}{2}a=x$.

Now therefore we have a Rule to determine the greater part of a given Quantity to be divided in Mean and Extreme Reason, viz. if the given Quantity be a Line, e. g. $AB=a$ (Fig. 58.) join to it (a) at Right Angles $AC=\frac{1}{2}a$: Wherefore by the Theorem of Pythagoras from Schol. Definir. 13. the Hypotenuse CB , or, which is equal to it, $CD=\sqrt{\frac{5}{4}aa}$; and consequently $AC=\frac{1}{2}a$ being taken out of CD , the Remainder AD , or AE , which is equal to it, will be $=x$, the greatest part sought; according to Euclid, whose Invention this first

Specimen of Analysis, by way of Anticipation, reduces to its original Fountain. As for Numbers (tho none accurately admits of this Section) the sense of the Rule, or which is all one as to the thing it self, is this: Add the Squares of a whole Number and its half, and subtract the said half from the Root of the Sum (which can't be had exactly, since it is $\sqrt{\frac{5}{4}}$.

(a) Eucl. 11.
lib. 11. 3
30. lib. vi.

C A A P. V.

Of the Proportion or Reasons of Magnitudes of the same kind in particular.

Proposition XXVIII.

Triangles and Parallelograms, also Pyramids and Prisms and Paralepipeds, lastly Cones and Cylinders, each kind compared among themselves, if they have the same Altitude, are in the same Proportion to one another as their Bases.

Demonstration.

This and the following Proposition might have been by bare Subsumption added, as *Confectarys* to the precedent; for the Altitudes in the one, and Bases in the other, may be looked on as common Efficients, and the Magnitudes mentioned as their Products: But for the greater distinction sake, we will thus Demonstrate them more particularly.

- I. If the equal Altitudes of two Triangles, or
 (a) *Euc. Prop.* (a) two Parallelograms, are called b and the
 1. *lib. vi.* Base of the one a , and of the other ea ; then
 (b) *Prop. 5.6.* Products will be ba and bea , the other $\frac{2}{3} ba$ and
lib. xii. 25, $\frac{2}{3} bea$, by *Def. 28. Schol. 2.*
 32. *xi. E*
Conf. 30 E
 31 of the same
 (c) *Prop. 11.* II. Likewise the equal Altitudes of two Prisms
lib. xii. (c) or Pyramids, may be called b , and the Pro-
 (d) *Prop. 35,* portion of their Bases expressed by a and ea ; and
 36, 37, 38, the Prisms will be among themselves as ba to bea ,
 39, 40, *lib.* and the Pyramids as $\frac{2}{3} ba$ to $\frac{2}{3} bea$, by the *fac.*
lib. I E 29, *Schol. Num. 3.*
 30, 31. *lib. xi.* III. There is also the same Proportion of Cylinders and Cones as of Pyramids and Prisms, by
Confect. 4. Definit. 17. But,

as a to ea so is ba to bea .

— $\frac{1}{2}ba$ to $\frac{1}{2}bea$.

— $\frac{1}{3}ba$ to $\frac{1}{3}bea$.

Q. E. D.

CONSECTARY.

Therefore Magnitudes of the same kind upon the same or equal Bases (Δ) and of the same height, are equal among themselves, and the contrary.

Proposition XXIX.

Triangles and Parallelograms, Pyramids and Prisms and Parallelepipeds, Cones and Cylinders, being on equal Bases, are in the same Proportion as their heights. (*)

Demonstration.

Let all their Bases be called a , and the Proportions of their Heights be as b to eb : Therefore, 1. the Parallelograms, Parallelepipeds and Cylinders, are one to the other of the same kind, as ba to eba ; the Triangles as $\frac{1}{2}ba$ to $\frac{1}{2}eba$; the Pyramids and Cones as $\frac{1}{3}ba$ to $\frac{1}{3}eba$, by Def. 28. Schol. 2. But, as b to eb , so is ba to eba .

and $\frac{1}{2}ba$ to $\frac{1}{2}eba$.

and $\frac{1}{3}ba$ to $\frac{1}{3}eba$.

Q. E. D.

Proposition XXX.

Equal (||) Triangles, Parallelograms, Prisms, Parallelepipeds, also equal Pyramids, Cones, and Cylinders, have their Bases and Heights reciprocally Proportional.

Demonstration.

For if for the equal Triangles you put $\frac{1}{2}ab$, for the Cones and Pyramids $\frac{1}{3}ab$, and for the rest ab ;

whether the Bases of the equal Quantities are supposed to be a , and so the Altitudes

(*) Schol prop.

12. 11, and its
Coroll. also
Prop. 15.

on

on both sides b ; or if the Base of the one be a and b the Altitude, but the Base of the other b and the Altitude a , you'll certainly have eitherways,

as a to a , so Reciprocally b to b ;

the Base of the former to the Base of the latter, as the Altitude of the latter to the Altitude of the former, or,

as a to b , so Reciprocally a to b . Q.E.D.

CONSECTARY.

AND those Magnitudes of the same kind, whose Bases and Altitudes are thus Reciprocal, are equal by *Prop. 18* for the Product or Rectangle of the Extremes is ab , and that of the Means ba .

Proposition XXXI.

Triangles, Parallelograms, Prisms, Parallelepipeds, Pyramids, Cones and Cylinders, each kind compared among themselves, are in the Proportion compounded of the Proportion of their Altitudes and Bases. (a)

Demonstration.

Suppose the Base of the one to be a , and the other ea , and the Altitude of the one b , of the other ib ; therefore the one will be to the other,

as $a b$ to $eiab$,

or $\frac{1}{2} ab$ to $\frac{1}{2} eiab$,

or $\frac{1}{3} ab$ to $\frac{1}{3} eiab$; i. e. every where as a to ea ,

i. e. in Proportion compounded of a to ea , and of b to ib , by

Consect. 2. Def. 34. Q.E.D.

SCHOLIUM.

From what we have hitherto Demonstrated, we may now only make an estimate of Magnitudes of the same kind compared together, which is easie to any one who attentively considers them; but also with *F. Morgues*, deduce

(a) *Prop. 23. lib. 6.* a General Rule of expressing the Proportions of any Rectilinear Planes or Solids, contained under

Planes

Plane Surfaces, by the proportion of one Right Line to another. For since the one may be resolved into Triangles, and the other into Pyramids, having first two Rectilinear Planes given and thus resolved, upon a Right Line I make the $\triangle abc$ (Fig. 49.) Equal to one of the Triangles of either of the Planes *e. g.* to $\triangle ABC$; then having drawn the Parallel cm , if the $\triangle BCD$ has the same Altitude with the former, you need only joyn the Base BC to the Base ab . But if the Altitude DS is greater than the Altitude of the other *e. g.* by $\frac{1}{3}$, then you must make bf equal to the Base bc augmented by a fifth part, and the Triangle bcf will $= BCD$, and the whole $acf =$ to the Rectilinear Figure $ABCD$. It now therefore I likewise make another Triangle ghi equal to another Rectilinear Figure between the same Parallels, then will the $\triangle acf$ be to the $\triangle ghi$, that is, the Right Lined Figure $ABCD$ to the Right Lined Figure $FGHIK$, as af to gh , by *Prop. 28.* 2. Having 2 Right Lined Solids given, and having resolved them into Triangular Pyramids, they may be transferr'd between 2 parallel Planes, *viz.* by augmenting or diminishing their Triangular Bases reciprocally, according to the excess or defect of their Altitudes, as was done above with the Linear Bases; then those Triangular Bases on both sides may be converted into one Triangular Base, and consequently each Solid into a Pyramid equal to it self; which two Pyramids will be one to the other as their Triangular Bases. And because the Proportions of these Bases may be reduced to the Proportion of two Lines each to the other, by *N^o 1.* of this; therefore also the Reason or Proportion of the two Solids may be expressed by the Proportion of two Lines. Q.E.D.

Proposition XXXII.

Circles (β) are in the same Proportion to one another as the Squares of their Diameters.

Demonstration.

Suppose a to be the Diameter of one Circle, and b of another; then by *Definit. 31. Consect. 1.* (β) *Eucl. Prop. 2. 6. 12.* the Area of the one will be $\frac{1}{4} eaa$, and that of the other $\frac{1}{4} ebb$. But as aa to bb so is $\frac{1}{4} eaa$ to $\frac{1}{4} ebb$ by *Consect. 1. Prop. 19.* Q. E. D.

CON-

CONSECTARY I.

THe same will in like manner be manifest of like Sectors of Circles, while for the parts of the Periphery you put i and b , as for the wholes we put ea and ob : for thus the Area of the one will be $\frac{1}{4}iaa$, and of the other $\frac{1}{4}ibb$.

CONSECTARY II.

Cylinders whose Altitudes are equal to the Diameters of their Bases, are in proportion to one another as the Cubes of their Diameters; for the Cylinders will be $\frac{1}{4}ea^3$ and $\frac{1}{4}eb^3$, the Cubes a^3 and b^3 .

CONSECTARY III.

Hence also (whatever the Reason of the Sphere is to the Cylinder of the same Diameter and Height; which will hereafter Demonstrate, and which in the mean while will denote by the name of the Reason y) I say, hence Spheres which have the same Proportion to one another as these Cylinders (*viz.* as $\frac{1}{4}ea^3$ to $\frac{1}{4}eb^3$, so $\frac{1}{4}yea^3$ to $\frac{1}{4}yeb^3$) will also (by Consect. I.) be in the same proportion as the Cubes, a^3 to b^3 ; which is also evident from these Terms themselves.

Proposition XXXIII.

THE Angle (β) at the Center of any Circle ACB (Fig. 60) is to an Angle at the Circumference which has the same Arch for its Base ADB, as 2 to 1.

Demonstration.

The truth of this has already appear'd from
 (a) Prop. 18 Schol. Definit. 10. N^o 3. but here we will demon-
 strate it otherwise in its three Cases, after Eu-
 clids way. In the first Case DE being conceiv'd
 (b) Eucl. Parallel to CB, by Def. 11. Consect. 1 and 2. the
 Prop. 20. l. 3. External Angle ACB is = to the Internal Angle

gle ADE, and the Angle BDE, is equal to the alternate Angle BCD, *i. e.* to the other at the Base CDB, by *Consect. 2. Definit. 13.* Therefore BDE is as 1, and CDE, *i. e.* ACB as 2.

In the second Case the whole ECB is double of the whole EDB, and the subtracted Angle ECA is double of the subtracted Angle EDA, by Case 1. Therefore the Remainder ACB is also double of the Remainder ADB, by Prop. 26. In the third Case the part ECA is double of the part EDA, and also the part ECB is double of the part EDB, by Case 1. Therefore the whole ACB is double the whole ADB. Q.E.D.

CONSECTARYS.

I. **H**ence all Angles ADB (α) in the same Segment are equal, and the Angle ADB (*Fig. 61.*) in a Semicircle is a Right one; because the Aperture at the Center answering to it, ACB contains two Right Angles: The Angle in a less Segment than a Semicircle EDF, is greater than a Right one; because the Aperture at the Center EGHC answering to it, comprehends more than two Right Angles. An Angle, lastly, in a Segment greater than a Semicircle GDH, is less than a Right one; because its double at the Center GCH is less than two Right ones. All which we have already otherwise demonstrated in *Schol. Def. 10. N^o 6.*

II. All the three Angles (β) of any Triangle ABD taken together, are equal to two Right ones; because they are the half of the three at the Center C, (α) *Eucl. prop. 21. 27. 31. Consect. 2.* *lib. 3.* (β) *prop. 32. 1.*

III. Therefore any external Angle IAB, is equal to the two Internal opposite ones at B and D; because that, as well as they with the other contiguous to them BAD, make two Right ones, by *Consect. 1. of the same Definit.*

IV. And the greatest Side of a Triangle, because it insists on a (α) greater Arch of a Circumscribed Circle, does also necessarily subtend a greater Angle, by virtue of *Consect. 1. hereof.*

Proposition

Proposition XXXIV.

IN Equiangular Triangles (ACB and abc , Fig. 62.) the Sides about the equal Angles are Proportional, viz. as AB to BC , so is bc , and as BC to CA so is bc to ca . &c. (β)

Demonstration.

For having described Circles thro' the Vertex of each Triangle, according to *Consect. 6. Definit. 8.* by reason of the supposed equality of the Angles A and a , B and b , C and c , the Arches also AB and ab , &c. will necessarily agree in the number of Degrees and Minutes, by the foregoing 33 *Prop.* so also the Chords AB and ab , BC and bc , &c. will agree in the number of Parts of the Radius or whole Sine ZA and za , *Consect. 2. Definit. 10.* Wherefore as many such Parts as AB has, whereof $a\chi$ has also 10000000, so many such also will ab have, whereof $a\chi$ has also 10000000, &c. Therefore AC to CB as ac to cb , &c. Q. E. D.

CONSECTAYS.

I. **W**herefore by the same necessity the Bases of such Triangles AB and ab , will be proportional to their Altitudes CD and cd , as being Right Sines of the like Arches CE and ce , or rather CE and ce ; and so for similar or like Triangles (and consequently also Parallelograms) we may rightly suppose that their Bases are as a to ea , and their Heights as b to eb ; tho we must not immediately conclude on the contrary, because their Bases and Altitudes are so, therefore they are similar.

II. As also in Similar Parallelepipeds it will be manifest to any attentive Person, that the Bases are in a duplicate Proportion of the Altitudes. For since the Planes of Similar Solids are equal in number, and Similar each to the other, if for ABC (Fig. 63.) we put a , and for BCb , AB will $= ea$ and $BC = eb$; and so that Basis will be to this as ab to $eeab$. Moreover having let fall the Perpendiculars EH and eh , the Triangle

$\triangle B H$ and $\triangle C B H$ are similar, and by putting c for $B C$, $B E$ will be $e c$, putting also d for $C B$, $E H$ will consequently be $e d$. But the Reason of the Base $a b$ to the Base $e e a b$, is duplicate of the Reason of d to $e d$, by *Def.* 34. Wherefore in Similar Parallelepipeds we may rightly suppose, that their Bases are as $a b$ to $e e a b$, or as a to $e e a$, and their Altitudes as d to $e d$.

SCHOLIUM I.

From this Proposition flows first of all the chiefest part of Trigonometry for the Resolution of Right Angled $\triangle A$: For since in any Right Angled Triangle, if one side, *e. g.* $A B$ (*Fig.* 64.) be put for the whole Sine, the other $B C$ will be the Tangent of the opposite Angle at A (and in like manner if $C B$ be the whole Sine, $B A$ will be the Tangent of the Angle C ;) but if the Hypotenuse $A C$ be made Radius or whole Sine, then the Side $B C$ will be the Right Sine of the Angle A , or the Arch $C D$ described from the Center A , and $A B$ the Right Sine of the Angle C , or the Arch $A E$, described from the Center C , (we will omit mentioning the Secants, because the business may be done without them) which all follow from *Def.* 10. Wherefore you may find,

I. The Angles.

- | | | |
|----------------------------------|------------------|---|
| 1. From the Sides | { by inferring } | As one leg to the other, so the whole Sine |
| | | to the Tangent of the Angle opposite to the other Leg. |
| 2. From the Hypoth., & one side. | | As the Hyp. to the W.S. (whole sine) so the given leg to the S. of the opp. angle |

II. The Sides.

- | | | |
|---|-----|---|
| 1. From the Hypoth. and Angles: | { } | As the W. S. to the Hypoth. so the Sine of the Angle, opposite to the Leg sought, to the Leg it self. |
| 2. From one Leg and the Angles: | | As the W. S. to the given Leg, so the Tangent of the Angle adjacent to it, to the Leg sought. |
| 3. From the Hypoth. and one of the Sides: | | Having first found the Angles, it's done by the 2, 1. or by the <i>Pythagorick</i> Theorem. |

H

III.

1. From the Angles and one of the Legs. } As the S. of the Angle, oppoſite to the given Leg, to that Leg, ſo the W. S. to the Hypoth.
2. From the Legs given; } Having firſt found the Angles its done by the 1. or by the *Pythagorick* Theorem.

III. Inverſly alſo, if two Triangles ABC and ABC (the Figure of the preſent Propoſition) have one Angle of one equal to one Angle of the other (e.g. B and B) and the Sides that contain theſe equal Angles proportional (*viz.* as AB to AB ſo AB to BC) then the other Angles (A and A , C and C) will be alſo equal, and the Triangles ſimilar (α) for to ſuch like Chords AB and AB , BC and BC , there anſwer by the Hypoth. like or ſimilar Arches, *i. e.* equal in the number Degrees and Minutes; and to theſe alſo there anſwer equal Angles both at the Periphery and Center.

IV. (*Fig. 65. N^o 1.*) If (β) the Sides of the Angle BAC are cut by a Line DE , parallel to the Baſe BC , the Segments thoſe Sides will be proportional, *viz.* AE to EC as AD to BD for by reaſon of the Paralleliſm of the Lines BE and BC , the Triangles ADE and ABC are Equiangular: Therefore as the whole BA to the whole AC , ſo the part AD to the part AB and conſequently alſo the remainder EC to the remainder DB as the part EA to the part AD , by *Prop. 26.* and alternatively by *Prop. 24.* EC will be to EA as BD to AD .

SCHOLIUM II.

Here are ſeveral uſeful Geometrical Practices depend on this *Conſectary* and its *Propoſition*. 1. That (γ) where

- (α) *Eucl. prop. 2.* we are taught to cut off any part required, *e. g.* $\frac{1}{3}$ from a given Line AB , and ſo generally to cut off or divide any given Line AC , in the ſame proportion as any other given Line, is ſuppoſed to be divided in D , (and conſequently into as many equal parts as you pleaſe;) *viz.* if in the firſt Caſe, having drawn any Line AF , you take AD 1, and make DB 2, and having joined CB , draw
- (β) *Eucl. 2. lib. 6.*
- (γ) *Eucl. 1. lib. 6.*
- 9 & 10. 1. 6.

the Parallel LE: for as AD to DB so is AE to AC; that is, as 1 to 2, by this 4th *Consect.* therefore AE is one third of the whole AC, &c.

II. A Rule (α) to find a third Proportional to the 2 Right Lines given AB and BC (N^o 2. *Fig. 65.*) (or a fourth to three given;) if, *viz.* having drawn AF at pleasure, you make AD equal to BC, and Joining DB, draw the Parallel EC: For as AB to BC, so AD *i. e.* BC to DE. Now if AD be not equal to BC but to another (*viz. a*) third Proportional, then by the same Reason DE will be a fourth Proportional.

III. Another Rule (β) to find a mean Proportional between two Right Lines given AC and CB; which is done by joining both the Lines together, and from the middle of the whole AB describing a Semicircle, and from C erecting the Perpendicular CD: For since the Angle ADB is a Right one, by *Consect. 1.* of the preceding *Proposition*, and the two Angles at C are Right ones, and those at A and B common to the whole Triangle ADB, and to the two partial ones ACD and BCD, these two will be Equiangular and Similar to the great one, and consequently to one another: Therefore by the present *Proposition*, as AC to CD, so CD to CB, Q. E. D. and also as AB to BD so BD to BC, and as AB to AD so AD to AC, &c.

IV. The Analytical Praxis of multiplying and dividing Lines by Lines, so that the Product or Quotient may be a Line; and also the way of Extracting Roots out of Lines: Which *Des Cartes*, gives us, p. 2. of his *Geom. viz.* assuming a certain Line for Unity, *e. g.* AB (in *Fig. 65.* N^o 2.) if AC is to be multiplied by AD, having joined BD, and drawn the Parallel CE, the Product will be AE; for it will be as 1 to the Multiplier AD, so the Multiplicand AC to the Product AE; or if AE is to be divided by AC, having joined EC and drawn the Parallel BD, the Quotient will be AD; (for AC the Divisor, will be to AE the Dividend, as an Unit AB to the Quotient AD;) all which are evident from the Nature of Multiplication and Division, and the

(α) *Eucl. 11*

3 12, l. 6.

(β) *Eucl. 13.*

lib. 6 3 and

Eucl. 8. lib. 6.

Precedent Praxes. As also taking CB (in the same Fig. N^o 3.) for Unity, if the Square Root is to be extracted out of any other Line AC, this being joined to your Unity in one Line AB and having described thereon a Semicircle, the Perpendicular CD will be the Root sought, as being a Mean Proportional betwixt the two Extremes CB and AC, according to Prop. 17.

V. A Right Line AG which divides (α) any given Angle A into two equal Parts (Fig. 66.) being prolonged, divides the Base BC proportionally to the Legs of the Angle AB and AC. For having prolonged CA to E, so that AE shall be $=$ to AB, the Angles ABE and AEB will be equal, by *Consect. 2. Def. 1.* and consequently also equal to each of the halves of the external Angle CAB, by *Consect. 3.* of the antecedent Proposition. Therefore the lines AG and EB will be parallel, by *Conf. 1. Def. 1.* Therefore as AC to AE, *i. e.* to AB, so GC to GB, by *Conf. 3.* of this Proposition. Q.E.D.

VI. Hence also there follows further, by conversion of the last inference, as $AC+AB$ to AC, so $GC+GB$ (*i. e.* BC) to GC; and inversely GC to BC as AC to $AC+AB$; and lastly alternatively, GC to AC as BC to $AC+AB$.

N. B. This last Inference follows also immediately from the preceding *Consectary*. For by reason of the Similitude of the $\Delta\Delta$ ACG and ECB, as GC to AC so BC to CE, *i. e.* to $AC+AB$.

SCHOLIUM III.

(α) *Eucl. 3. lib. 6.* FROM these two last *Consectarys* there arise these or two or three Practical Rules, the first whereof shews, how having the two Legs AB and AC given, and also the Base BC, to find the Segments GC and GB, made by the Bisection of the Intercrural Angle (*viz.* by this inference, according to *Consect. 6.* As the Sum of the Sides to one Side (*e. g.*) AC :) so the Sum of the Segments of the Base, *i. e.* the whole Base to one of the Segments, so that next the said Side GC. 2. It shews on the contrary, how having the Base and one of its Segments given, and moreover the Sum of the Sides, to find separately the Side AC next the known Segment

by inferring as the Sum of the Segments, or the Base BC to the Sum of the Sides, so the given Segment GC to the sought AC: or also, 3dly, *Having only the Base and Sum of the Sides given*, but not the Segment GC, yet to express its Proportion to the next side AC, — — — viz. in the Quantities of the given Terms, by putting (by *Consect. 6.*) for GC the value of the Base BC, and for AC the value of the Sum $AB + AC$; the great use of which last Rule will appear hereafter in the Cyclometry (or Quadrature of the Circle) of *Archimedes*.

VII. In any Triangle ABC (*Fig. of the present Proposition*) the Sides are to one another as the Sines of their opposite Angles: For they are as the Chords of the double Angles at the Center, by *Prop. 33.* therefore they are also one to another as half those Chords, i. e. by *Definit. 10.* as the Sines of the half Angles.

SCHOLIUM IV.

Hence flow two new Rules of Plane Trigonometry, for Oblique-angled Triangles to find, viz.

I. The other Angles:

From 2 given Sides, & an Angle opposite to one of them :	} by inferring	As the Side opposite to the given Angle to the other Side, so is the Sine of the given Angle to the sine of the angle opposite to the other Side; which being given, the third is easily found.
--	----------------	---

II. The other Sides:

From one side and the angles given,	} As the Sine of the Angle opposite to the given side, to that side; so is the Sine of the Angle opposite to the side sought to the side sought.
-------------------------------------	--

So that this way we have reduced all the Cases excepting one of Plane Trigonometry, and consequently all *Euthymetry* to their original Foundations (for in that Case of having two Sides, and the included Angle given, we may find the rest by

the Resolution of the Obliqueangled Triangle into two Right Angled ones; and so it's done by the Rules we have deduc'd in (*Schol. 1.*) I say, excepting one, in which from the three sides of an Obliqueangled Triangle given, you are required to find the Angles: the Rule to resolve which we will hereafter deduce in the 2d *Consect.* of *Prop. 45.* from that Theorem which *Euclid* gives us, *lib. 2. Prop. 13.*

VIII. Because in in the Right Angled $\triangle BAC$ (*Fig. 67.*) BC is to CA as CA to CD , by N^o 3. of the 2d *Schol.* of this *Prop.* the \square of CA will be $= \square CE$, by *Prop. 17.* In like manner because as CB to BA so is BA to BD ; the \square of BA will be $=$ to $\square BE$: Wherefore the two Rectangles BE and CE taken together, that is, the \square of the Hypothenufe BC , will be $=$ to the two \square 's BA and CA taken together: Which is the very Theorem of *Pythagoras* demonstrated two other ways in *Schol.* of *Definit. 13.*

SCHOLIUM V.

THIS Theorem of *Pythagoras* as it furnishes us with Rules of adding Squares into one Sum, or subtracting one Square from another; so likewise it helps us to some Foundations whereon, among the rest, the structure of the Tables of Sines relies, &c. Whose use we have already partly shewn in *Schol. 1* and 4. 1. If several Squares are to be collected into one Sum, having joined the Sides of two of them so as to form a Right Angle, e.g. AB and BC (*Fig. 68. N^o 1.*) the Hypothenufe AC being drawn, is the Side of a Square equal to them both; and if this Hypothenufe AC be removed from B to D , and the Side of the third Square from B to E , the new Hypothenufe DE will be the Side of a Square equal to the three former taken together. 2. If the Square of the side MN (N^o 2.) is to be subtracted from the Square of the side LM . Having described a Semicircle upon LM , and placed the other MN within that Semicircle, then draw the Line LN and that will be the Side of the remaining Square. 3. Having the Right Sine EG of any Arch ED given (but how to find the Primary Sines we will shew in another place) you may obtain the Sine Complement CG or EF , by the preceding

Numb. viz. by subtracting the \square of the given Sine from the \square of the Radius ; and moreover the versed Sine GD by subtracting the Sine Complement CG from the Radius CD. 4. The Squares of the versed Sine GD, and of the Right sine EG being added together, give the \square of the Chord ED of the same Arch, (which all are evident from the *Pythagorick Theorem*) and half of that EH gives the Right Sine of half that Arch. 5. From the Right Sine EG you have the Tangent of that Arch, if you make, as the Sine Complement CG to the Right Sine GE, so the whole Sine CD to the Tangent GI. 6. Lastly, From these *Data* you may also have the Secants (if required) thus, as the Sine Complement CG to the W. S. CE, so the W. S. CD to the Secant CI ; or as the Right Sine EG to the W. S. EC, so the Tangent ID to the Secant IC ; both which are evident by our 34th Proposition.

Consect. 9. If the Quadrant of a Circle (CBEG, Fig. 70.) be inclined to another Quadrant (CADG) and two other Perpendicular Quadrants cut both of them, *viz.* FBAG and FEDG, and the latter do so in the extremities of them both) having let fall Perpendiculars from the common Sections E and B, thro' the Planes of the Perpendicular Quadrants, and the inclined Quadrant, (*viz.* on the one side EG and BH, as Right Sines of the Segments EC and BC ; on the other EI and BK, as Right Sines of the Segments ED and BA) you'll have 2 Triangles EIG and BKH Right Angled at I and K, Equiangular at G and H (by reason of the same inclination of the Plane CBEGC) and consequently similar, by our 34th Proposition ; wherefore as the Sine EG to the Sine EI, so the Sine BH to the sine BK, or as EG to BH so EI to BK, and contrariwise.

SCHOLIUM VI.

Hence you have several Rules of *Spherical Trigonometry* for resolving Right Angled $\Delta\Delta$ (α) 1. Having given in the Rightangled Δ ABC the Hypothenufe BC and the Oblique Angle ACB, for the Leg AB opposite to this Angle. make : as the sine T (EG) to the sine of the Hypoth. (BH) so the sine of the given Angle (EI) to the sine of the Leg sought (BK). 2. Having given the Hypothe-

(α) *Lansberg. Geom. Triang. lib. 4. Prop. 12.*

nuse BC and the Leg AB for the opposite Angle ACB make as the sine Hypoth. (BH) to S. T. (EC) so the sine of the given Leg (BK) to the sine of the Angle sought (EI) 3. Having given the side AB and the Angle opposite to it ACB for the Hypothenuse BC (supposing you know whether it be greater or less than a Quadrant) make as the sine of the given Angle EI to the sine T. (EG) so the sine of the given Leg (BK) to the sine of the Hypoth. BH). 4. Having given in the Right Angled \triangle EBF (which we take instead of ABC that so we may not be obliged to change the Figure) one Leg EB and the Hypothenuse BF for the other Leg EF, you may find its complement, if you make as the sine Complement of the given side (BH) to S. T. (EG) so the sine Complement of the Hypothenuse (BK) to the sine Compl. of the side sought (EI) 5. Having both Legs EB and EF given, for the Hypothenuse BF its Compl. BA may be found thus: as S. T. (EG) is to the sine Cmpl. (BH) of one side EB, so the sine Compl. (EI) of the other side (EF) to (BK) the sine Compl. of the Hypothenuse.

6. Having given in the same Right Angled Triangle EBF one Leg EF, and the Angle adjacent to it ETB, first prolong into whole Quadrants BA to *f*, that Af may = BF Hypoth. & BC to *e* that Ce may = EB, and AC to *d* that Cd may = DE the measure of the given Angle EFB: secondly from *d* thro' *e* and *f* let fall a Quadrant thro' the extremities of the Quadrant Bf and Be, that so the $\triangle Cde$ may be Right Angled, in which there are given the Hypoth. Cd = to the given Angle, and the Angles C = to the Compl. of the given Leg (viz. to the Arch ED) and so, thirdly, there is sought the side *de*, or the Complement of the Arch *ef*, or of the Angle sought ABC or EBF; viz. by the first case of this, by inferring, as S. T. to the sine Hypoth. *cd* (i.e. of the given Angle EFB;) so the Angle *dce* (i.e. DE the Compl. of the given Leg RF) to the sine *de* (as the Compl. of the Angle *fBe* or EBF.)

7. Having given, in the same Triangle, the side EF and the opposite Angle EBF (i.e. the Arch *ef*) for the other Angle EFB (that is the Hypoth. *cd* in the $\triangle cde$) make by the third of this:

As the Sine of the Angle *dce* (i.e. the sine Compl. of the given Leg DE) to the S. T. so the sine of the Leg *dc* (i.e. the

fine Compl. of the Angle EBF) to the Hypoth. cd (i.e. the fine of the Arch DA or Angle EFB.).

8. Having the Oblique Angles given to find either of the sides, viz. EF; which may be done thus by the second of this:

As the fine of the Hypoth. cd (i.e. the fine of the Angle at F) to the W. S. so the fine de (i.e. the fine Compl. of the Angle at B) to the fine of the Angle dce (i.e. the fine Compl. of the side sought EF.)

Consect. 10. The same being given as in Consect. 7. if instead of the Right Sines EI and BK, you erect Perpendicularly DL and AM (Fig. 71) because of the similitude of the Triangles DGL and AHM, you'll have, as DG fine T. to DL the Tangent of the Arch DE, so AH the Right Sine of the Arch AC to AM the Tangent of the Arch AB; or as DG to AH, so DL to AM, and contrariwise.

SCHOLIUM VII.

Hence flow the other Rules of *Spherical Trigonometry* for Resolving Right Angled Triangles, viz. 9. Having given the side AC in the $\triangle ABC$, and the adjacent Angle ACB, for the other side AB, make as the W.S. (DG) to the fine of the given side (AH) so the Tangent of the given Angle (ACB) to the Tangent of the Angle sought (AB.) 10. Having given the side (AB) and the opposite Angle (at C) for the other side (AC, so you know whether it be greater or less than a Quadrant) make as the Tangent of the given Angle (DL) to the Tangent of the given Leg (AB) so the whole S. (DG) to the fine of the Leg sought (viz. at AH.) 11. Both sides being given, for the Angles, make, as the fine of one Leg (AH) to the W. S. (DG) so the T. of the other Leg (AM) to the Tangent of the Angle opposite to the same (at C.) 12. Having given moreover in the Right Angled Triangle EBF the Hypothenuse (BF) and the Angle (EFB) for the adjacent side EF, make, as the fine Compl. of the given Angle (AH) to the W. S. so the Tangent Compl. of the Hypoth. (AM) to the Tang. Compl. of the Leg sought (DL) 13. Having given the side (EF) and the adjacent Angle F for the Hypoth. BF make; as the W. S. to the fine Compl. of the given Angle (AH) so the Tangent Complement of the given Leg (DL)

to the Tangent Compl. of the Hypoth. (AM.) 14. Having given the Hypoth. (BF) and one side EF for the adjacent Angle (F) make as the Tang. Compl. of the given Leg (D.L.) to the W. S. so the Tang. Compl. of the Hypoth. (AM) to the Sine Compl. of the Angle sought (AH). 15. Having given the Hypoth. (BF, *i. e.* the arch Af, or the angle at d) and either of the oblique angles (at F) for the other angle (EBF) make by help of the new Triangle *cde*, by the 12th of this.

As the Sine Compl. of the angle *cde* (*i. e.* the Sine Compl. of the Hypoth. (AH) to the W. S. so the Tang. Compl. of the Hypoth. *cd* (*i. e.* Tang. Compl. of the given angle) to the Tang. Compl. of the Side *de* (*i. e.* to the Tang. of the angle sought ABC or EBF.)

16. Having given the oblique Angles to find the Hypoth. (BF, or the arch Af, or the angle *cde*) it is done by the 14 of this *Schol.*

As the Tang. Compl. of the Leg *de* (*i. e.* the Tangent of the angle ABC or EBF) to the W. S. so the Tangent Complement of the Hypoth. *cd* (*i. e.* the Tangent Complement of the other angle EBF) to the Sine Compl. of the angle *cde* (*i. e.* the Sine Compl. of the Hypoth. BC sought.)

So that now we have with *Lansbergius* (but much more compendiously) Scientifically Resolved all the Cases of Right-angled Triangles; the Resolution of Oblique-angled ones only now remaining.

Consect. 11. In Oblique-angled Spherical Triangles, as well as Right-angled ones, the Sines of the angles are directly proportional to the Sines of the opposite Sides. 1. Of the Right-angled ones this is evident from N^o 3. *Schol.* 6. and from the 9th *Consect.* For as the Sine of the angle A (*Fig.* 72.) to the Sine of BD, so the W. S. (*i. e.* of the angle D) to the Sine of AB. 2. The same is immediately evident of an Oblique-angled Triangle ABC, resolved into 2 Right-angled ones. For,

The Sine of the angle C is to the Sine of BD as the sine of the angle D to the Sine of AB; and also,

The Sine of the angle C to the Sine of BD as the Sine of the angle D to the sine of BC, by the 1.

In each Proportionality the means are the Sines of BD and D; therefore the Rectangles of the Extremes of the Sines of AB into the Sine of A, and the Sine of BC into the Sine of C, will be equal among themselves, since the Rectangles of the same Means are equal, by *Prop.* 18. therefore by *Prop.* 19. as the Sine of A to the Sine of BC, so the Sine of C to the Sine of AB, Q.E. D.

SCHOLIUM VIII.

THE latter may appear of Oblique-angled Triangles after this way also; since the Sine of the angle A is to the Sine of BD as the Sine of the angle D to the sine of AB, call the first *a*, the second *e a*, the third *b*, the fourth *e b*; and because the Sine of the angle C (which we call *c*) is likewise to the Sine of BD (*i. e.* to *e a*) as the Sine of D (*i. e.* *b*) to the Sine of BC (which will consequently be $\frac{e a b}{c}$) it will be manifest, that the Sine of the angle

A is to the sine of BC as the sine of the angle C to the sine of AB,
i. e. as *a* to . . . $\frac{e a b}{c}$, *i. e.* . . . *c* to . . . *e b*.

by multiplying the Means and Extremes, whose Rectangles are on both sides *e a b*. Therefore as by the present and precedent *Confessary* 7, it is universally true, That in any Triangle whether Right Lined or Spherical, Right-Angled or Oblique-angled, the Sides or their Sines, are to one another, as the Sines of their opposite Angles (which therefore is commonly called a *Common Theorem*;) so also hence flow 2 new Rules of *Spherical Trigonometry* for Oblique-angled Triangles, like those we found in *Schol.* 4.

To find

I. The other Angles.

From 2 sides } by inferring { As the sine of the side opposite to the given of an angle opposite to } the sine of the other side, so }
 one of them, } angle sought.

II. The

II. The other Sides.

From one side and the angles given, } by inferring } As the sine of the angle opposite to the given side to the sine of that side, so the sine of the angle opposite to the side sought to the sine of the side sought.

And thus we have reduced all the Cases and Rules of Spherical Trigonometry to their original Fountains (for from 1 Sides given and the interjacent Angle, or 2 Angles and their adjacent side, we may find the rest in Oblique-angled Triangles by resolving them into 2 Right-angled ones; and so by the Rules we have deduc'd in *Schol.* 6 and 7) excepting two Cases, *viz.* when from 3 sides given, the Angles, or from 2 Angles the Sides are sought; to resolve which, we are supplied with Rules from the following

Conf. 12. In the given Oblique-angled Spherical Triangle ABC (*Fig.* 73.) whose Sides are unequal and each less than a Quadrant, having produced the sides AB and AC to the Quadrant AD and AE, and effected besides what the Figure directs, there will

The Arch DE be the Measure of the angle A, $AF=AC$, and so FB the difference of the Sides AB and AC.

$BC=BG$, and so GF the difference of the third side, and the differences of the rest FB.

But now, 1. As EH or DH to CM or FM so will PH be to NM (by reason of the Equiangular Triangles EPH and CNM;) therefore by *Prop.* 26. so will also DP be to FN. Make therefore $DH=a$ $FM=ea$, $DP=b$ $FN=eb$.

AI the R. Sine of the side AB.
CM the Sine of the Side AC.
GL the Sine of GB, or of the side BC.

FK the R. Sine of the Arch FB.
BI the versed Sine of AB.

BL the vers. Sine of GB or BC.
BK the versed Sine of FB.

KL or NO the difference of the versed Sines we have now mentioned.

EP the Right Sine and DP the versed Sine of the arch DE.

CN the R. Sine and FN the versed Sine of the arch FC.

2
FNO

ver
the

2. By reason of the Equiangular $\Delta\Delta$ FNO and HAI (for FNO is Equiangular to the Δ FKQ, and that to the Δ HQM, by reason of the Vertical Angles at Q; and that also to the Δ HAI by reason of the Common Angle at H) and you have also,

As HA,

Or DH to AI, so FN to NO.

$$a - oa - eb - oeb.$$

Wherefore now, 3. you'll have evidently,
the \square DH to FM into AI as DP to NO.

$$\begin{array}{ccccccc} aa & \text{---} & oea & \text{---} & b & \text{---} & oeb. \\ \text{i.e. } a & \text{---} & oea & \text{---} & b & \text{---} & oeb. \\ & & DH & & NO & & DP. \end{array}$$

And Inversly as oea to a so oeb to b .

SCHOLIUM IX.

Since therefore the Radius DH or a is known, and also NO the Difference of the versed Sines BL and BK , it is evident, that DP the versed Sine of the angle A will be known also; supposing that the first Quantity oea is likewise known. But this may be had by another Antecedent Inference, if you make,

as AH to FM so AI to a fourth oea .

$$a \quad ea \quad oa$$

Hence therefore arises, 1. the Rule: Having given the 3 Sides of an Oblique-angled Triangle, to find any one of the Angles, viz. by inferring,

1. As the Sine of T to the Sine of R , one of the sides comprehending AC ; so the sine of the other side AB to a fourth,

DH or AH — FM — AI — oea .

$$a - ea - oa.$$

2. As this fourth to the sine of T , so the difference of the versed sines of the third side, BC , and the differences of the others to the versed sine of the Angle sought, viz.

$$\begin{array}{ccccccc} oea & \text{---} & a & \text{---} & NO & \text{---} & DP. \\ & & & & oeb & & b. \end{array}$$

But since the sides of a Spherical Triangle may be changed into

into Angles, and contrariwise the sides being continued [as the side AB of the given Triangle ABC (Fig. 47.) be continued a Circle, the rest into Semicircles from the Poles *b* and *c* and likewise the Semicircle HI from the Pole A, and the Semicircle FG from the Pole B, and the Semicircle EA from the Pole C, you'll have a new Triangle *a, b, c*, the 3 angles of which will be equal to the 3 sides of the former ABC; as the angle *a* or its measure IG, is equal to the side AB, by reason each makes a Quadrant joined with the third arch AG; but the measure of the angle *b*, is the side AC (*viz.* in this case wherein the side AC is a Quadrant, in the other wherein it would be greater or less than a Quadrant, it would be the measure of the angle of the Compl. for then the Semicircle HI described from the Pole A, would not pass thro' C but beyond or on one side of C. See *Pitisc. lib. 1. Prop. 61. p. m.* 24.) ——— the angle *c* or its measure KL, is equal to the side BC, because with the third KC they make the Quadrants BK and CL] Therefore, 2. Having given the three Angles of the Oblique-angled Triangle *abc*, you may find any side, *a, b, c*, if there be sought the Angle ABC, or rather its Complement KBF, or its measure $FK = ac$, ——— from the 3 sides given of the Δ ABC, by the preceding Rule, by intersecting, *viz.* 1. As S. T. to the sine R, of one side comprehending the angle of one side AB (*i.e.* of one angle *a* adjacent to the side sought) so the sine of the other side BC (*i.e.* of the other angle C) to a fourth.

2. As the fourth to the S. T. so the difference of the versed Sines of the third side AC, and the differences of the other two (*i.e.* of the 3d angle *b*, and the differences of the rest) to the versed Sine of the comprehended angle, or Complement to a Semicircle (*i.e.* of the side sought *ac*.)

Proposition XXXV.

Similar Plane Figures (*a*) are to one another in Duplicate Proportion of their Homologous Sides.

Demonstration.

For, 1. the Bases of 2. similar Triangles or Parallelograms

for which any 2 Homologous Sides, e. g. AB and \overline{AB} (Fig. 75.) may be taken) and Perpendiculars let fall thereon DE and \overline{DE} , will be by *Consect. 1. Prop. 34*, as a to ea , b to eb . Therefore the Parallelograms and Triangles themselves, will be as ba to $eeba$, by *Consect. 7* and *8. Def. 12. i. e.* by *Def. 34.* in Duplicate Reason of their Perpendiculars or assumed Sides, which is most conspicuous in Squares, which putting a for the Side of one, and ea for the other, are to one another as aa to $eeaa$.

2. Like Polygons are resolved into like Triangles, when the Triangles ABC and \overline{ABC} , and (a) *Eucl. 19* also AED and \overline{AED} are Equiangular, by *Consect. 3. Prop. 34.* but CAD and \overline{CAD} , are also Equiangular, because each of their angles are the remainder of equal ones, after equal ones are taken from them. Wherefore the first Triangles are in duplicate Proportion of the sides BC and \overline{BC} ; the second likewise of the sides CD and \overline{CD} the third are also in the same Proportion of the sides DE and \overline{DE} , &c. i. e. (since by the Hypoth. BC has the same reason to \overline{BC} as CD to \overline{CD} , and DE to \overline{DE}) each to each is in duplicate Proportion of the sides BC to \overline{BC} , or CD to \overline{CD} , by the first of this: Therefore by a Syllepsis, the whole Polygons are in duplicate Proportion of the same Sides: Which is the second thing to be demonstrated.

3. Circles and their like Sectors, are as the Squares of their Diameters, by *Prop. 32.* therefore in duplicate Proportion of them, by the first of this: Which is the third thing: Therefore similar Plane Figures, &c. Q. E. D.

CONSECTARYS.

I. **T**herefore 2 similar Plane Figures are one to another, as the first Homologous Side, to a third Proportional, by vertue of *Definition 34.*

II. Any two Figures described on 4 Proportional Lines (a) and similar to 2 others, are likewise Proportional, and contrariwise; for if the simple Reasons or Proportions of Lines be the same, their duplicate Proportions will be the same also, and reciprocally. (a) *Eucl. prop. 22. lib. 6.*

SCHO-

SCHOLIUM.

BUT as this second Confectary confirms Prop. 22 and Scholium, so the first teaches us a twofold Geometric Praxis. 1. A Way to express the Proportion of similar Figures by two Right Lines, viz. by finding a third Proportional to their Homologous Sides. For as the side of the first to this third, so will be the first Figure to the second. 2. A way to augment or diminish any given Figure in a given Ratio or Proportion, viz. by finding a mean Proportional between any side of the given Figure, and another Line which shall be to that in a given Proportion, and then by describing thereon a similar or like Figure.

Proposition XXXVI.

Similar or like Solid Figures, are to one another in triplicate Proportion of their Homologous Sides.

Demonstration.

For, 1. The similar Bases of two similar Parallelepipeds (and consequently also of Prisms and Cylinders, by Consect. 1 and 5. Definit. 16. and also of Pyramids and Cones, by Consect. 3 and 4, of Definit. 17.) are, as ab to $eeab$, by (α) the preceding Proposition, and their Altitudes as c to ec , by Consect. Prop. 34.

Therefore Parallelepipeds, Cylinders and Prisms (and so the third part of these, Cones and Pyramids) will be as abc to e^3abc , by Consect. 3, 4, 5. Definit. 16. i. e. they will be, by Definit. 34. Consect. 1 and 2. Prop. 34. in Triplicate Proportion of their Perpendiculars or Homologous Sides. Which is especially conspicuous in Cubes; which, putting a for the Side of one, and ea for the side, are to one another as a^3 to e^3a^3 .

2. Polyedrous or many sided Figures, may be resolved into Pyramids of similar Bases and Altitudes; which is evident of Regular ones, from the Consect. of Definit. 21. and cannot be difficult to understand also of Irregular ones; because the like inclination

Inclination of their Planes every where similar and equal in number, necessarily require that the whole Altitudes of similar Polyedrous Solids, as well as similar Parallelepipedons, by *Consect. 2. Prop. 34.* should be in subduplicate Proportion of their Bases, and so these being likewise divided in C and C (Fig. 76. N^o 1.) the parts of their heights GC and CC, will be in the same Proportion: Whence, *e. g.* 2 Pyramids standing on similar Bases ABDEF and ABDEF, and having like Altitudes GC and CC, will necessarily be like or similar; and the same thing may be likewise judged of others.

Or yet, to shew it more evidently, the Polyedrous Solids may be resolved into like Triangular Prisms; for, *e. g.* each of the Triangles of their similar Bases ABDEF and ABDEF (N^o 2.) are similar, *viz.* abf and abf , ABF and ABF , by the preceding *Prop. N^o 2.* The Planes $ABba$ and $ABba$, also $AafF$ and $AafF$, are similar by the Hypoth. and consequently also the Planes $BbfF$ and $BbfF$ (fb is to ba as fb to ba , and also in the one ba to bB , as ba to bB in the other; therefore *ex equo* as fb to bB so fb to bB , &c.) and so the whole Triangular Prisms will be similar, by *Definit. 35.* and so of others. Therefore similar Polyedrous Solids will be in the same Proportion as similar Pyramids, or Triangular Prisms, *i. e.* by the first of this in Triplicate Proportion of their Sides.

3. Spheres are as the Cubes of their Diameters (β) by *Consect. 3. Prop. 32.* Therefore they are by the first of this, as a^3 to $e^3 a^3$. Therefore similar or like Solids are in Triplicate Proportion of their Homologous Sides. Q. E. D.

(α) *Eucl. prop. 12. lib. 12. of Cones and Cylinders.*

(β) *Eucl. 18, lib. 12.*

C H A P. VI.

Of the Proportions of Magnitudes of divers sorts compared together.

Proposition XXXVII.

THE Parallelogram $ABCD$ (Fig. 77. N. 1.) is to the Triangle BCD upon the same base DC , and of the same height as 2 to 1. This has been already Demonstrated in *Consect.* 3. *Dem.* 12. Here we shall give you another

Demonstration.

Suppose, 1. the whole Base CD divided into four equal parts by the transverse Parallel Lines EG , HK , LN , then will (by reason of the similitude of the $\Delta\Delta$ DGF , DKI , DNM , DCB .) GF be 1, KI 2, NM 3, CB 4; and having further more continually Bisected the Parts of the Base, the Indivisibles or the Portions of the Lines drawn transversely thro' the Triangle will be 1, 2, 3, 4, 5, 6, 7, 8, &c. *ad infinitum*, all along in an Arithmetical Progression, beginning from the Point D , as 0; to which the like number of Indivisibles always answer in the Parallelogram equal to the greatest, *viz.* the Line BC . Wherefore by the 4th *Consect.* of *Prop.* 16. all the Indivisibles of the Triangle, to all those of the Parallelogram taken together, *i. e.* the Triangle it self to the Parallelogram, is as 1 to 2. Q. E. D.

S C H O L I U M.

NOW if any one should doubt whether the Triangle or Parallelogram may be rightly said to consist of an infinite number of Indivisible Lines, he may, with Dr. Wallis, insist

instead of Lines, conceive infinitely little Parallelograms of the same infinitely little Heighth, and it will do as well. For having cut the Base (N^o 2) into 4. equal parts by transverse Parallels, there will be circumscribed about the Triangle so many Parallelograms of equal heighth, being in the same Proportion as their Bases, by *Prop. 28. i. e.* increasing in Arithmetical Progression. In the following Bisection, there will arise 8 such Parallelograms approaching nearer to the Triangle, in the next 16, &c. so that at length infinite such Parallelograms of infinitely less heighth, and ending in the Triangle itself, will constitute or make an infinite Series of Arithmetical Proportionals, beginning not from 0 but 1; to which there will answer in the Parallelogram infinite little Parallelograms of the same heighth, equal to the greatest. Whence it again follows, by *Consect. 9. Prop. 21.* that the one Series is to the other, *i. e.* the Triangle to the Parallelogram as 1 to 2; which being here thus once explained, may be the more easily applied to Cases of the like nature hereafter.

CONSECTARYS.

I. Since in like manner in the Circle (*Fig. 79.*) the Peripherys at equal intervals from one another, as so many Elements of the Circle, increase in Arithmetical Progression; the Sum of these Elements, *i. e.* the Circle it self will be to the Sum of as many Terms equal to the greatest Periphery, *i. e.* to a Cylindrical Surface, whose Base is the greatest Periphery, and its Altitude the Semidiameter, as 1 to 2.

II. Hence the Curve Surface of a Cylinder circumscribed about a Sphere, *i. e.* whose Altitude is equal to the Diameter, is Quadruple to its Base.

III. Also the Sector of the Circle *bac*, to a Cylindrical Surface, whose Base is the Arch *bc*, but its Altitude the Semidiameter *ac*, is as 1 to 2.

IV. And because the Surface of the Cone BCD is to its circular Base, as BC to CA, *i. e.* as the $\sqrt{2}$ to 1. by *Schol. Prop. 17.* the Cylindrical Surface, the Conical Surface and the Circular

cular one we have hitherto made use of will be as 2, $\sqrt{2}$ and 1, and consequently continually Proportional.

SCHOLIUM

ALL which may also abundantly appear this way, by putting for the Diameter of the Circle a , for the Semidiameter $\frac{1}{2}a$ and for the Circumference ea , you'll have the Area of the Circle $\frac{1}{4}eaa$ by *Consect. 1. Definit. 31.* and Multiplying the height of the Cylinder AB i.e. $\frac{1}{2}a$ by the Periphery ea you'll have the Cylindrical Surface $\frac{1}{2}eaa$ by *Consect. 6. Definit. 18.* as now is evident also by *Consect. 1, 2 and 3.* Now if you would also have the Surface of the Cone, since it's side by the *Pythagorick Theorem* is $\sqrt{\frac{1}{2}aa}$ and the half of that $\frac{1}{2}\sqrt{\frac{1}{2}aa}$ i.e. (by *Nº 2 of Schol. Prop. 22.*) $\sqrt{\frac{1}{8}aa}$; and this half being multiplied by the Periphery of the Base ea , you'll have (by virtue of *Consect. 4. Definit. 18.*) the Surface of the Cone $ea\sqrt{\frac{1}{8}aa}$ i.e. (by the *Schol.* just now cited) $\sqrt{\frac{1}{8}eaaa}$; So that now appears also the 4th *Consect.* of this; because the Rectangle of those Extremes eaa and $\frac{1}{4}eaa$ is $\frac{1}{8}eaaa$ as well as the square of the mean.

Proposition XXXVIII.

A Parallelepiped (α) BF (Fig. 77. *Nº 3.*) is to a Pyramid $ABCDE$ upon the same Base BD and of the same height, as 3 to 1. This was Demonstrated in *Consect. 3. Definit. 17.* but here we shall give you another.

Demonstration.

Suppose 1 the whole Altitude BE divided into 3 equal Parts by transverse Plains Parallel to the Base, then will (by reason of the Similitude of the Pyramids $abcd E$ ~~$ACBD$~~ and $AECDE$) the Bases $abcd$ ~~$ABCD$~~ and $ABCD$ be by *Consect. 2. Prop. 34* and *Consect. 3. Definit. 17* in duplicate Proportion of the Altitudes i.e. in duplicate Arithmetical Progression 1, 4, 9, moreover 2, bisecting the parts of the Altitude, the quadrangular Sections now double in Number (as the Indivisibles Elements of the proposed Pyramid) will be as 1, 4, 9, 16, 25

36, &c. *ad Infinitum*, all along in a duplicate Arithmetical Proportion; while in the mean time there answer to them as many Elements in the Parallelepiped equal to the greatest ABCD, wherefore by *Consect. 10. Prop. 21.* all the Indivisibles of the Pyramid taken together will be to all the Indivisibles of the Parallelepiped also taken together, *i. e.* the Pyramid it self to the Parallelepiped, as 1 to 3. Q. E. D.

CONSECTARY.

THIS Demonstration may be easily accommodated to all other Pyramids and Prisms, and also Cones and Cylinders, (α) since here also (*Fig. 78.*) the circular Planes *ba*, *Ba*, and *BA* are as the squares of the Diameters, (α) *Euclid. Prop. 10. lib. 12.* and so as 1, 4, 9. and so likewise all the other Elements of the Cone by continual bisection are in duplicate Arithmetical Progression; when in the mean time there answer to them in the Cylinder as many Elements equal to the greatest *BA*, &c.

Proposition XXXIX.

A Cylinder is to a Sphere inscribed in it *i. e.* of the same Base and Altitude as 3 to 2.

Demonstration.

Suppose 1 (*Fig. 80*) the half Altitude GH (for the same proportion which will hold when demonstrated of the half Cylinder AK and Hemisphere AGB, will also hold the same of the whole Cylinder to the whole Sphere) to be divided into 3 equal parts, then will AH, C1, E 2, be mean proportionals between the Segments of the Diameter by *Prop. 34 Schol. 2 N^o 3.* and so by *Prop. 17.* the Rectangles LHG, L1 G, L2G equal to the Squares AH, C1, E2, being in order as 9 8 and 5. and also 2dly. having bisected the former parts of the height, the six Squares cutting the Sphere Cross ways will be found to be as 36, 35, 32, 27, 20, 11. &c. in the progression we have shewn at large in *Consect. 12. Prop. 21.* Wherefore since all the Indivisibles of the Hemisphere, *viz.* the circular Planes answering to the Squares of the said Hemisphere

Diameters have the same proportion of Progression, by Prop. 32. and there answer to them the like number of Elements in the Cylinder equal to the greatest AH: All these taken together will be to all the other taken together i. e. the whole Cylinder AK to the whole Hemisphere AGB by virtue of the aforesaid Coroll. 12. as 3 to 2 (α) Q. E. D.

SCHOLIUM. 1.

HONORATUS Fabri elegantly deduces this Prop. *a priori*, in a geometrick Method in his *Synopsis Geom.* p. 318. (which CAROLUS RENALDINUS performs from the same common Foundation *lib. 1. de Compos. and Resol.* p. 301, and the following, but after a more obscure way and from a demonstration further fetched) Fabri's is after this Method: The whole Figure (81) AL being turned round about BZ, the Quadrant ADLBA will describe a Hemisphere, the Square AZ a Cylinder and the triangle BLM a Cone all of the same Base and Altitude. Since therefore Circles are as the squares of their Diameters by Prop. 32. and the Square of GE = to the Squares of GD and GF taken together (i. e. the Square of GF i. e. $GB \times \square GD$ is = $\square BD$ or BA or GE by the *Pythag. Theor.*) and so the Circle described by GE will be = to 2 Circles described by GD and GF taken together then taking away the Common Circle described by GF there will remain the circle described by GF within the Cone equal to the Annulus or Ring described by DE about the Sphere. And since this may be demonstrated after the same way in any other case, viz. that a circle described by *gf*, will be equal to an Annulus described by *de*; it will follow, that all Rings or Annuli described by the Lines DE or *de* (i. e. all that Solid that is conceived to be described by the trilinear Figure ADLM turned round) will be equal to all the Circles described by GF or *gf* (i. e. to the Cone generated by the Triangle BLM;) and so as the Cone is $\frac{1}{3}$ part of the Cylinder generated by AL, by the Coroll. of Prop. 38. so also the Solid made by the Trilinear ADLM (viz. the Excess of the Cylinder above the Sphere) will be $\frac{1}{3}$ of the Cylinder, and consequently the Hemisphere Q. E. D.

CONSECTAYS.

Hence you have a further Confirmation of *Consect. 2. Prop. 32.* and *Prop. 36. N. 3.*

II. Hence also naturally flows a Confirmation of *Consect. 2. Definit. 20.* and consequently the Dimension of the Sphere both as to its solidity and Surface. For putting a for the Diameter of the Sphere and circumscribed Cylinder, and Ea for the Circumference, the Basis of the greatest Circle will be $\frac{1}{4} eaa$, and that multiplied by the Altitude, gives $\frac{1}{4} ea^3$ for the Cylinder. Therefore by the present Proposition, $\frac{1}{2} ea^3$ gives the Solidity of the Sphere (by making as 3 to 2 so $\frac{1}{4}$ to $\frac{1}{2}$) This divided by $\frac{1}{2} a$, will give, by virtue of *Consect. 1.* of the aforesaid *Def. 20.* and *Consect. 3. Definit. 17.* the Surface of the Sphere aaa .

III. Therefore the (α) Surface of the Sphere aaa , is manifestly Quadruple of the greatest Circle $\frac{1}{4} eaa$.

IV. The Surface of the Cylinder, without the Bases, made by multiplying the Altitude a by the Circular Periphery of the Base ea , will be eea , equal to the Surface of the Sphere.

V. Adding therefore the 2 Bases, each whereof is $\frac{1}{4} eaa$, the whole Surface of the Cylinder $1 \frac{1}{2} eaa$, will be to the Surface of the Sphere aaa as 3 to 2.

VI. The Square of the Diameter aa to the Area of the Circle $\frac{1}{4} eaa$, is as a to $\frac{1}{4} ea$, i. e. as the Diameter to the 4th part of the circumference.

VII. A Cone of the same Base and Altitude with the Sphere and Cylinder, will be by *Consect. 2.* of this, *Prop.* and the *Consect.* of *Prop. 38.* $\frac{1}{2} ea^3$, and of the Cylinders $\frac{1}{4}$ or $1 \frac{3}{4} ea^3$. Therefore a Cone, Sphere, and Cylinder, of the same height and diameter, are as 1, 2, 3. The Cone therefore

(α) *Archim.* is equal to the Excess of the Cylinder above the
lib. 1. *de Sph.* Sphere; as is otherwise evident in *Scholium 1.*
& *Cylind.* of this.

Prop. 31. (al. 30).

I 4

And

SCHOLIUM II.

AND thus we have briefly and directly demonstrated the chief Propositions of *Archimedes*, in his 1. Book de Sphaera et Cyli. which he has deduced by a tedious Apparatus, and only indirectly. And now if you have a mind to Survey the longer and more perplex way of *Archimedes*, and compare it with this shorter cut we have given you; take it thus: *Archimedes* thought it necessary first of all to premise this Lemma; That all the Conical Surfaces of the Conical Body made by Circumvolution of the Polygon, or many-angled Figure A, B, C, D, E &c. (Fig. 82.) inscribed in a Circle, according to *Definit.* 10. I say, those Conical Surfaces taken all together, will be equal to a Circle, whose Radius is a mean Proportional between the Diameter AE and a transverse Line BE , drawn from one extremity of the Diameter E to the end of the side AB next to the other extremity. This we will thus demonstrate by the help of specious Arithmerick: Since BN , HN are the Right Sines of equal Arches, CK and CK whole Sines, &c. and the Lines BH , GC , &c. parallel; having drawn obliquely the transverse Lines HC , GD , all the angles at H , C , G , D , &c. will be equal by *Consect.* 1. *Definit.* 11. and consequently all the Triangles BNA , HNI , ICK , &c. equiangular, both among themselves, and to the $\triangle ABE$; since the angle at B is a Right one, by *Consect.* 1. *Prop.* 33. and the angle at A common with the $\triangle BNA$. Wherefore as BN to NA so CK to CI .

or HN to NI so CK to KL .

and so DM to ML so EB to BA ; and so FM to ME

by making BN , HN , DM , $FM = a$ CK and $CK = b$, $EB = c$, for NA , NI , ML and ME , you may rightly put a for KL and $KL = b$ for AB , &c. Which being done you may easily obtain the Conical Surfaces of the inscrib'd Solid, and the Area of a Circle whose Radius shall be a mean Proportional between AE and EB , and it will be evidently manifest, that these two are equal. For, 1. (for Conical Surfaces) the Diameter of the Base $BH = 2a$, and the side of the Cone $AB = c$. Therefore (making here d the name of the Reason between the Diameter and Circumference) the circumference will be $2ad$ which

which multiplied by half the side $\frac{1}{2}ec$, gives the Conical Surface $eaec$, by *Consect. 4. Definit. 18.* And since the Circumference BH is as before $2oa$, and the circumference $CG = 2ob$, half of the sum $2oa + 2ob$, viz. $oa + ob$ is the equated Circumference: which multiplied by the Side $BC = ec$ gives the Surface of the truncated Cone $BHGC = eaec - obec$, by *Consect. 5.* of the aforesaid *Def.* since, lastly, the Surface of the truncated Cone $DFGC$ is equal to one, and likewise the conical Surface EDF to the other, by adding you'll have the Sum of all $4eaec + 2obec$.

2. (for the Area of the Circle) the Diameter AE is $= 4ea + 2eb$, and $BE = c$: the Rectangle of these is $= 4eac + 2ebc =$ (which also is evidently equal to the Rectangle of all the transverse Lines BH, CG, DF into the side AB , as *Archimedes* proposes in the matter) $=$ to the Square of the Radius in the Circle sought, because the Radius is a mean Proportional between AE and BE , and so equal to $\sqrt{4eac + 2ebc}$, so that the whole Diameter is $2\sqrt{4eac + 2ebc}$. Therefore, 2. the circumference of this Circle will be $20\sqrt{4eac + 2ebc}$, i.e. $\sqrt{1600eac + 800ebc}$: which multiplied by half the Semidiameter, i.e. by $\frac{1}{2}\sqrt{4eac + 2ebc}$, i.e. $\sqrt{eac + \frac{1}{2}ebc}$ gives the Area of the Circle sought $\sqrt{1600eac + 800ebc} + 400eeabcc + 400eebbcc$. But this Root extracted is $40aec + 2obec$, equal to the superiour Sum of the conical Surfaces. Q.E.D.

Having thus demonstrated the Lemma, we will easily demonstrate with *Archimedes* (tho not after his way) That the Surface of any Sphere, is Quadruple of the greatest Circle in it, which is already evident from the 3d *Consect.* For since all the conical Surfaces of the inscribed Solid taken together, by the preceding Lemma, are equal to the Area of a Circle whose Radius is a mean Proportional between the Diameter AE and the Transverse EB ; and this mean Proportional approaches always so much nearer to the Diameter AE , and those Surfaces so much nearer to the Surface of the Sphere, by how many the more sides the inscribed Figure is conceived to have, by *Consect. 1 and 2. Def. 18.* if you conceive in your mind the Bisection of the Arches $AB, BC, &c.$ to be continued in *Infinitum*, it will necessarily follow, that all those conical Surfaces will at length end in the Surface of the Sphere it self, and that mean

Pro-

portional in the diameter AE, and so the Surface of the Sphere will be equal to a Circle, whose Radius is the Diameter AE. But that Circle would be Quadruple of the greatest Circle in the present Sphere, by *Prop.* 35. Therefore the Surface of the Sphere is Quadruple of that Circle also. Q. E. D.

Hence also it would be very easie to deduce with *Archimedes* (tho again after another way) that celebrated Proposition, which we have already demonstrated from another Principle in the *Prop.* of this Schol. *viz.* That a Cylinder is to a Sphere of the same Diameter and Altitude, as 3 to 2. For by putting a for the Diameter and Altitude, and $e a$ for the Circumference, the Area of the Circle, will be $\frac{1}{4} e a a$; and this Area being multiplied by the Altitude a , gives $\frac{1}{4} e a^3$ for the Cylinder, by *Consect.* 5. *Definit.* 16. and the same Quadruple, *i. e.* $e a a$ multiplied by $\frac{1}{2} a$ gives $\frac{1}{2} e a^3$ for the Sphere, by *Consect.* 1. *Definit.* 20. and *Consect.* 3. *Definit.* 17. Wherefore the Cylinder will be to the Sphere as $\frac{1}{4}$ to $\frac{1}{2}$, *i. e.* in the same Denominator as $\frac{1}{4}$ to $\frac{1}{2}$, *i. e.* as 6 to 4, or 3 to 2. Q.E.D.

Whence it is evident, that the Dimension of the Sphere would be every ways absolute if the Proportion of the Diameter to the Circumference were known; which now with *Archimedes* we will endeavour to Investigate.

Proposition XL.

THE Proportion of the Periphery of a Circle (a) to the Diameter, is less than $3\frac{1}{7}$ or $\frac{10}{7}$ to 1. and greater than $3\frac{1}{11}$ to 1.

Demonstration.

The whole force of this Proposition consists in these, that, 1. Any Figure circumscribed about a Circle, has a greater Periphery than the Circle, but any inscrib'd one a less. 2. The Periphery of a circumscribed Figure of 96 sides, has a less Proportion to the Diameter, than $3\frac{1}{7}$ to 1.

To demonstrate this second, we will enquire (a) *Archim.* 3. the Proportion of one side of such a Figure whether circumscribed or inscribed after the following way.

For the first part of the Proposition.

Suppose the Arch BC (Fig. 84. N. 1.) of 30 degrees, and its Tangent BC making with the Radius AC a Right Angle, to make the Triangle ABC half of an Equilateral one, so that AB shall be to BC in double Reason, viz. as 1000 to 500; which being supposed, AC will be the Root of the Difference of the Squares BC and AB, i. e. a little greater than 866, but not quite 1000.

Then continually Bisectiong the Angles BAC by AG, GAC by AH, HAC by AK, KAC by AL, BC is half the side of a circumscribed Hexagon, GC the half side of a Dodecagon (or 12 sided Figure) HC of a Polygon of 24 sides, KC of one of 48; lastly, LC of one of 96 sides; and by N. 3. Schol. 3. Prop. 34. GC will be to AC as BC to BA + AC, and also HC to AC as GC to GA + AC, &c. Wherefore

In the first Bisection, of what parts GC is 500, of the same will AC be 1866 and a little more, and AG (which is the Root of the Sum of the \square GC and AC) $1931\frac{8}{10}+$.

In the second Bisection, of what parts HC is 500, of the same will AC be found to be $3797\frac{8}{10}+$ and AH $3830\frac{5}{10}+$.

In the third Bisection, of what parts KL is 500 of the same will AC be $7628\frac{3}{10}+$ and AK $7644\frac{6}{10}+$.

In the 4th Bisection, of what parts LC is 500 of the same will AC be $15272\frac{2}{10}+$.

Now therefore LC taken 96 times, will give 48000 the Semi-periphery of the Polygon, which has the same Proportion to the Semi-diameter AC $15272\frac{2}{10}$ as the whole Periphery to the whole Diameter. But 48000 contains $15272\frac{2}{10}$, 3 times, and moreover $2181\frac{3}{10}$ remaining parts, which are less than $\frac{1}{7}$ part of the division, for multiplied by 7 they give only $1526\frac{1}{10}+$.

Therefore it is evident, that the Periphery of this Polygon (and much more the Periphery of a less Circle than that) will have a less Proportion to the Diameter, than $3\frac{1}{7}$ to 1. Which is one thing we were to demonstrate.

For

For the 2d Part of the Prop.

Suppose the Arch BC to be (N^o 2.) of 60 Degr. that is the Angle BAC at the Periphery of 30 Since the Angle at B is a right one by *Consect. 1. Prop. 33.* the Triangle ABC will be again half an Equilateral one, and BC the whole side of an Hexagon, and GC of a Dodecagon, &c. So that putting for BC 1000 (as before we put 500 for the side of the Hexagon) let AC be 2000 and AB the Root of the difference of the Squares BC and AC *i. e.* less than $1732\frac{1}{10}$ viz. 1732 and not quite $\frac{6}{100}$.

Then bisecting continually the Angles BAC, GAC, &c. since the Angles at the Periphery BAG, GAC, GCB, standing on equal Arches BG and GC, are equal by *Prop. 33.* and the Angle at C, (common to the Triangles GCF and GCA) and the others at H, K, L are all right ones by *Consect. 1.* of the aforesaid *Prop.* these 2 Triangles CGF and CGA are equiangular and consequently by *Prop. 34.* the Perpendicular GC in the one will be to the Perpendicular GA in the other as the Hypotenuse CF in the one to the Hypoth. AC in the other *i. e.* (by the Foundation we have laid in the former part of the Demonstration of N^o 3, *Schol. 3. Prop. 34.*) as BC to AB + AC; and in like manner in the following HC will be to HA as GC to AG + AC, &c. Wherefore.

In the first Bisection, of what parts GC is 1000 of the same AG will be a little less than $3732\frac{1}{10}$; and AC (which is the Root of the Sum of the $\square\square$ AG and GC) will be a little less than $3863\frac{8}{10}$.

In the second Bisection, of what parts GC is 1000 of the same will AH be a little less than $7595\frac{2}{10}$ and AC a little less than $766\frac{4}{10}$.

In the third Bisection, of what parts KC is 1000 of the same will AK be a little less than $15257\frac{4}{10}$ and AC a little less than $15290\frac{7}{10}$.

In the fourth Bisection, of what parts LC is 1000 of the same will AL be a little less than $30547\frac{6}{10}$; and AC a little less than 30564, and consequently if LC be put 500, AC will be less than 15282.

Now

Now therefore LC taken 96 times will give 48000 for the Periphery of the inscrib'd Polygon, and 15282 and a little less for the Diameter AC. But 48000 contains 15282 thrice, and moreover a remainder of 2154 parts, which are more then $\frac{10}{71}$ of the Divisor; for $\frac{1}{71}$ of this number makes $215\frac{17}{71}$ and so $\frac{10}{71}$ makes $2150\frac{170}{71}$ i. e. $2152\frac{28}{71}$. Therefore it is evident that the Periphery of this Inscribed Polygon (and much more the Periphery of a Circle greater then that) will be to it's Diameter in a greater proportion then $3\frac{1}{71}$ to 1, which is the 2d thing.

SCHOLIUM

IF any one had rather make use of the small numbers of *Archimedes*, which he chose for this purpose, by putting in the first part of the Demonstration, for AB 306 and for BC 153, in the second for AC 1560 and for BC 780, by the like process of Demonstration, he may infer the same with *Archimedes*. We like our Numbers best, tho' somewhat large, because they may be remember'd, and are more proportionate to things, and make also the latter part of our Demonstration like the former. The Proportion in the mean while of the Diameter to the Periphery of the Circle by the *Archimedean* way is included within such narrow Limits, that they only differ from one another $\frac{1}{497}$ or $\frac{10}{4970}$ parts; for $\frac{10}{71}$ Subtracted from $\frac{10}{70}$ leave $\frac{1}{497}$, as $3\frac{10}{71}$ or $\frac{223}{71}$ and $3\frac{16}{70}$ or $\frac{220}{70}$ if they are reduced to the same Denomination make on the one hand $\frac{15610}{4970}$ on the other $\frac{15620}{4970}$. Hence it would be easy, having divided the difference $\frac{10}{4970}$ into 2 Parts, to express a middle proportion of the Periphery to the Diameter between the 2 *Archimedean* and Extreme ones as in these Numbers, 15610 to 4970, (or by dividing both sides by 5) as 3123 to 994, or (dividing both sides by 7) as $446\frac{1}{7}$ to 142, or (by dividing again by 2) as $223\frac{1}{14}$ to 71, &c.

While these Numbers become as fit for use as those of *Archimedes*, which we therefore use before any other, particularly in Dimensions that dont require an exact Niceness; where they do those may be made use of exhibited by *Ptolomey*, *Vieta*, *Ludolphus* a *Ceulea*, *Metius*, *Snellius*, *Lansbergius*, *Hugeus*, &c. as if

The Diameter be	The Circumference will be
10, 000, 000	31, 416, 666. <i>Ptolomey</i> ,
10 000, 000, 000	31, 415, 926, 535. <i>Vieta</i> .
100, 000, 000, 000, 000, 000 000	314, 159, 265,
358, 979, 323, $84(\frac{1}{2})$, &c. <i>Ludolph. a Ceulen</i> .	<i>Prop.</i>

Proposition XLI.

THe Area of a Circle has the same proportion to the Square of its Diameter, as the 4th part of the Circumference to the Diameter.

Demonstration.

Though we have before Demonstrated this Truth in *Confect. Prop. 39.* yet here we will give it you again after another way. Since therefore the Circumference is a little less then $3\frac{1}{2}$, and a little more than $3\frac{10}{11}$ Diameters, for this excess putting z if the Diameter be 1 we will call the Circumference $3+z$ therefore the 4th Part of it will be $\frac{3+z}{4}$. And the Area of the Circle (being Multiplied the half Semidiameter) *i. e.* $\frac{1}{4}$ by the Circumference, you'll have both $\frac{3+z}{4}$ and the square of the Diameter = 1 . Q. E. D.

CONSECTARY.

Therefore if the (α) Proportion of *Archimedes* be near enough truth to be made use of, *viz.* 22 to 7; the Area of the Circle will be to the Square of the Diameter as 11 to 14 because the quarter part of 22, *i. e.* $5\frac{1}{2}$ or $\frac{11}{2}$ to the Diameter $\frac{11}{2}$ is in the same Proportion.

Proposition XLII.

THE Diameter (β) of a Square AC (*Fig. 83.*) is incommensurable to the side AB (and consequently also to the whole Periphery) *i. e.* it bears a Proportion to that cannot be exactly expressed by Numbers.

(α) *Archim.*
Prop. 3. Cyclom.

(β) *Eucl. last*
Prop. lib. 10.

Demonstration.

For, if for AB you put 1, BC will be all

1, and by the Pythagorick Theorem AC will be $=\sqrt{2}$. Therefore by *Consect. 4. Definit. 30.* AC is incommensurable to the side AB, &c. Q.E.D.

CONSECTARY I.

IT is notwithstanding Commensurable in Power; for its Square is to the Square of the Side as 2 to 1.

CONSECTARY II.

NOW if the Proportion of the side or whole Periphery ABCDA, to the Diam. AC is to be expressed by Numbers somewhat near, as we have done in the Diameter and Circumference of a Circle; then making the side $AB=100$, the Diameter is greater than $141\frac{42}{100}$, less than $141\frac{43}{100}$.

Proposition XLIII.

THE Area of a Circle is Incommensurable to the Square of the Diameter.

Demonstration.

For dividing the Semidiameter CD (*Fig. 85.*) into two equal Parts (and consequently the Diameter DF into 4) AC will be 2, viz. $\sqrt{4}$ and AC $\sqrt{3}$, by *Schol. 2. Prop. 34. N. 3.* the sum $\sqrt{4}+\sqrt{3}$, and the sum of as many equal to the greatest AC 4. Having moreover Bisected the Parts of the Semidiameter, AC will $=4$ or the $\sqrt{16}$, $ac=\sqrt{15}$, $AC=\sqrt{12}$, $AC=\sqrt{7}$; the sum $\sqrt{16}+\sqrt{15}+\sqrt{12}+\sqrt{7}$; and the sum of as many equal to the greatest AC is $=16$, &c. And thus the last sums will be the Square Numbers increasing in Quadruple Proportion; but the former Sums will be always composed of the Rational Root of every such Square, and of several other irrational Roots of Numbers unevenly decreasing; so that it will be impossible to express those former Sums by any Rational Number, by what we have said in *Schol. 2. Definit. 30.* Wherefore all the Indivisibles of the Quadrant ADC are to as many of the Square ACDE equal to the greatest, i. e. the Quadrant itself ADC

ADC to the Square ACDE (and consequently the whole Area of the Circle to this circumscrib'd Square) will be as a Sürd Quantity to a true and truly Square Number, i. e. the Area of the Circle will be Incommensurable to the Square of the Diameter, by *Consect.* 4. of the said *Definit.* Q. E. D.

CONSECTARY.

AND because the fourth part of the Circumference has the same Proportion to the Diameter, as the Area of the Circle to the Square of the Diameter, by *Prop.* 41. Therefore also that will be Incommensurable to this, and consequently the whole Circumference will be so to the Diameter.

SCHOLIUM.

WHEREfore it is somewhat Wonderful, which G. G. Leibnitius (a) tells us, that the Square of the Diameter being 1, the Area of the Circle will be $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \frac{1}{11} + \frac{1}{13}$, &c. *ad Infinitum.* i. e. by adding $1, \frac{1}{5} - \frac{1}{3}$ and $+\frac{1}{9} - \frac{1}{7}$, &c. to $\frac{2}{3} + \frac{2}{35} + \frac{2}{99}$, &c. i. e. to the Sum of infinite Fractions whose common Numerator is 2. But their Denominators Squares less'd by Unity, and taken out of the Series of the Squares of Natural Numbers by every fourth, omitting the Intermediate ones: Which Sum might seem expressible in Numbers, since all its parts are Fractions reducible to a common Denominator; while notwithstanding Leibnitius himself confesses, that the Circle is not Commensurable to the Square, nor expressible by any Number.

(a) *Acta Erudit. Ann.*
82. p. 44 &
the following.

C H A P. VII.

Of the Powers of the Sides of Triangles, and other Regular Figures, &c.

Proposition XLIV.

IN Right-angled Triangles (*a*) (*ABC*, Fig. 86.) the Square of the Side (*BC*) that subtends the Right-angle, is equal to the Squares of the other Sides (*AB* and *AC*) taken together.

Demonstration.

Though we have demonstrated this Truth more than once in the foregoing Proposition; yet here we will confirm it again as follows. Having described on each side of the Square *BE* a Semicircle, which will all necessarily touch one another in one point, and be equal to the Semicircle, *BAC*, if you conceive as many Triangles inscribed also equal to *BAC*; it will be evident that the Square *BE* will contain the said 4 Triangles; and besides the little Square *FGHI*, whose side *FI*, *v. g.* is the difference between the greater side of the Triangle *CI*, and the less *CF*, (for because the less side *CF* = *BA*, lying in the first Semicircle, if it be continued to *I* in the second Semicircle makes *CI* = *CA* the greater side of the other Triangle, and so in the others. From thence it is evident, That as the Angles *ABC*, and *ACB* together make one right one; so likewise *BCF* (= *CBA*) and *ECF* make also one right one; and consequently *ECF* is = *ACB*, and the Arch and the Line *EI* = to the Arch and the Line *AB*, &c.) Wherefore, if the greatest side of the given Triangle *BC* or *BD*, &c. be called *a*, and *AC*, *b* and the least *AC*, or *CF*, &c. be called *c*; the Square of the side *BC*, will be = *aa*, and the Area of each Triangle $\frac{1}{2} b c$: and so the 4 Triangles together $2 b c$: but the side of the middle little Square will be $b - c$, and its Square $b b + c c - 2 b c$: Wherefore if you add to this the 4 Triangles

K

gles

The Sum of aa , *i.e.* the whole Square BE will be $bb + cc = aa$. Q. E. D.

CONSECTARYS.

I. **H**ence having the sides that comprehend the Right-angle given, $AC=b$ and $AB=c$, the Hypotenuse or Base that subtends the Right-angle BC will be $=\sqrt{bb+cc}$.

II. But if BC be given $=a$ and $AC=b$, and you are to find $AB=x$; because $xx+bb=aa$; you'll have (taking away from both sides bb) $xx=aa-bb$: therefore x , *i.e.* $AB=\sqrt{aa-bb}$.

III. If 2 Right-angled Triangles have their Hypotenuses and one Leg equal, the other will also be equal.

Proposition XLV.

IN Obtuse-angled Triangles (Fig. 87. N. 1. the Square of the Base or greatest Side BC that subtends the Obtuse-angle BAC, is equal to the Squares of (α) the other 2 Sides (AB and AC) taken together and also to 2 Rectangles (CAD) made by one of the Sides which contain the Obtuse-angle (AC) and the continuation AD to the Perpendicular BD let fall from the other side.

(α) Eucl. prop. 12. lib. 2.

Demonstration.

If BC be called a , $AB=c$, $AC=b$, $AD=x$, CD will be $=b+x$. Therefore $\square BD=cc-xx$, by Consect. 2. of the preceding Prop. In like manner if $\square CD=bb+2bx+xx$ be subtracted from the $\square BC=aa$, you'll have $aa-bb-2bx-xx$ to the same $\square BD$. Therefore

$$cc-xx=aa-bb-2bx-xx,$$

i.e. (adding on both sides xx)

$$cc+aa-bb-2bx.$$

i.e. (adding on both sides bb and $2bx$)

$$cc+bb+2bx=aa. \quad \text{Q. E. D.}$$

CONSECTARY.

IF in this last Equation you subtract from both Sides $cc+bb$ then will $2bx=aa-bb-cc$ and (if you moreover divide both Sides by $2b$) you'll have $\frac{x=aa-bb-cc}{2b}$ Which is the Rule, when you have the Sides of an Obtuse-angled Triangle given, to find the Segment AD, and consequently the Perpendicular BD.

Proposition XLVI.

IN Acute-angled Triangles (*a*) the Square of any side (e.g. B.C. Fig. 87. N. 1.) subtending any of the Angles, as A is equal to the Squares of the other 2 sides (AB and AC) taken together, less 2 Rectangles (CAD) made by one side, containing the Acute-angle (CA) and its Segment AD reaching from the Acute-angle (A) to the Perpendicular (BE), let fall from the other side.

Demonstration.

Make again $BC=a$, $AC=b$, $AB=c$, $AD=x$; then will $CD=b-x$. Therefore $cc-xx=\square BD$, and $aa-bb+2bbx-xx$ (*i. e.* $\square BC-\square CD$) will also be $=\square BD$.

Therefore $cc-xx=aa-bb+2bbx-xx$.

i. e. (adding to both sides xx)

$$cc=aa-bb+2bbx,$$

i. e. (adding on both sides bb , and subtracting $2bx$)

$$cc+bb+2bx=aa. \quad Q. E. D.$$

CONSECTARYS.

IF in the last Equation, except one, you add on both sides bb , and subtract aa , you'll have $cc+bb-aa=2bx$, and, if moreover you divide both sides by $2b$, you'll have

$$\frac{cc+bb-aa}{2b}=x: \text{ Which is the Rule, having 3}$$

sides given in an Acute-angled Triangle, to find the Segment AD, and consequently the Perpendicular BD. know;

Knowing therefore the Segments AD and CD, and also the Perpendicular BD in Oblique-angled Triangles, whether Obtuse-angled or Acute-angled, when moreover the sides BC and AB are likewise given, the Angles of either Right-angled Triangles or Oblique-angled ones, will be known; so that the last Case of Plane Trigonometry, which we deferr'd from Prop. 34 to this place, may hence receive its solution.

Proposition XLVII.

THE Square of the Tangent of a (α) Circle, is equal to a Rectangl^e contain'd under the whole Secant DA, and that part of it which is without the Circle DE, whether the Secant pass thro' the Centre or not.

Demonstration.

For in the first Case, if CB and CE are $= b$, DE $= x$, then will CD $= b + x$, & AD $= 2b + x$: therefore

(α) Eucl. 36
Lib. 3.

$\square ADE = 2bx + xx$ & $\square CD = bb + 2bx + xx$. therefore, if from the $\square CD$ you subtract $\square CE = bb$ the remainder will be $2bx + xx = \square BD = \square ADE$. Q. E. D.

In the second Case, the lines remaining as before, make DB $= y$, FE or FA $= z$: therefore the $\square ADE$ will be $= 2zy + yy$, but the $\square FC$ equal to the $\square EC - \square FE = bb - zz$ i. e. $2bx + xx + zz$. But the same Square FD is $= 2zy + yy$. Wherefore taking away from these equal Squares the common one zz you'll have $2zy + yy = 2bx + xx$ i. e. pr. 1st Case $= \square BD$. Q. E. D.

CONSECTARYS.

I. **T**herefore the Rectangles of diverse secants (as of AD & a de in Fig. 88, n. 1.) which are equal to the same Square. BD, are equal also to one another; which the last Equation in our Demonstration ($2zy + yy = 2bx + xx$) is an ocular proof of.

II. Therefore by Prop. 19. as aD to AD so is reciprocally DE to Dc in the Fig. of the 2 Case.

III. Tangents to the same Circle from the same Point, as DB & Dc (n. 3.) are equal; because the Square of each is equal to the same Rectangle.

IV. Nor can there be more Tangents drawn from the same point then two: For if besides DB & Dc , Dc could also touch the Circle, then it would be equal to them. By Conf. 2. but that is absurd by Conf. 3. Def. 7.

SCHOLIUM I.

Hence is evident, the Original of the Geometrical Constructions, which *Cartes* makes use of, p. 6, and 7. in resolving these 3 Equations, $zz = az + bb$, $zz = az + bb$, & $zz = az + bb$. For in the First case, since he makes NO or NL (Fig. 89. 11. 1.) or $NP \frac{1}{2} a$, and the Tangent $z Mb$, make MNO through the Center xx will $= Z$ the quantity sought; which thus appears: Making $MO = Z$, NM will $= Z \frac{1}{2} a$, and its $\square ZZ - aZ + \frac{1}{4} aa$. But the $\square OMP$ (which is by the present Prop. $= \square LM$, i. e. bb) together with the $\square NL$ or NP i. e. $\frac{1}{4} aa$ is $= \square NM$ by the *Pythagor. Theor.* Therefore $ZZ - aZ + \frac{1}{4} aa = bb + \frac{1}{4} aa$ i. e. (taking away from both sides $\frac{1}{4} aa$) $ZZ - aZ = bb$ i. e. (by adding on both sides aZ) $ZZ = aZ + bb$: Which is the Equation proposed. In the Second Case, if you make $PM = Z$ (as *Cartes* makes it) you'll have $\square NM + ZZ + aZ + \frac{1}{4} aa$, and to this again as before you'll have $= bb + \frac{1}{4} aa$. Therefore $ZZ + aZ = bb$: Therefore $ZZ = -aZ + bb$: Which is the very Equation of the Second Case. In the third Case, whether you make the whole Secant RM (N. 2) or that part of it without the Circle $QM = Z$, the Root sought, there will come out on both sides the same Equation of the third Case, and so it is manifest, that this Equation has those 2 Roots. For if RM be $= Z$ (adding $+$ to the Fig of *Cartes* the Line NO which shall bisect QR , and makes $OM = LN$) OR or OQ will be $= Z - \frac{1}{2} a$, and so the $\square OQ = ZZ - aZ + \frac{1}{4} aa$, and this together with the $\square RMQ$ (which is by virtue of the pres. Prop. $= \square LM$) $= \square NQ$ i. e. OM , i. e. $ZZ -$

$aZ + \frac{1}{2}aa + bb = \frac{1}{2}aa$, *i. e.* (by adding aZ and taking away $\frac{1}{2}aa$) $ZZ + bb = aZ$; *i. e.* (taking away bb) $ZZ = aZ - bb$. Which is the the very Equation of the third Case. But if QM be made $= Z$, OQ or OR will $= \frac{1}{2} - Z$, and its $\square = \frac{1}{2}aa - aZ + ZZ$, as well as the former, and so all the rest. Q. E. D.

SCHOLIUM. II.

NOW if you would immediately deduce these Rules by the present Proposition, without the *Pythagorick Theorem*. It may (*e. g.* in the first Case) be done much shorter thus: If $MO = Z$ and NO or $NP = \frac{1}{2}a$, then will $PM = Za$: Therefore $\square OMP = ZZ - aZ = bb$, or the $\square LM$, by the present Proposition; by adding therefore to both sides aZ , you'll have $ZZ = aZ + bb$, which is the very Equation of the first Case. In the second Case, if MR be Z , QM or PR will $= a - Z$: Therefore $\square RMP aZ - ZZ = bb$, *i. e.* $aZ = bb + ZZ$, *i. e.* $aZ - bb = ZZ$; but if $QM = Z$, RM will $= a - Z$. Therefore $\square RMP aZ - ZZ = bb$, as before, &c.

SCHOLIUM III.

FROM the 2 Consect. of the present Proposition, flows another Rule for solving the last Case of *Plain Trigonometry*, which we solved in the Consect. of the foregoing Prop. viz. If you have all the three sides of the Oblique-angled Triangle BCD (Fig. 96) given, if from the Center C , at the distance of the lesser side CB you describe a Circle, then will, by Consect. 2. of the present Proposition, BD the Base of the Triangle (here we call the greatest side of the Triangle the Base, or in an Equicrural Triangle, one of the greatest) will be to AD , (the sum of the Sides $DC + CB$) as DE the difference of the Sides, to DF the Segment of the Base without the Circle; which being found, if the remainder of the Base within the Circle be divided into two equal parts, you'll have both FG and GB , as also DG ; which being given, by help of the Right-angled $\triangle GBC$ and GDC all the Angles required may be found.

Propo-

Proposition XLVIII.

IN any Quadrilateral Figure (α) $ABCD$ (Fig. 91. N. 1.) inscribed in a Circle, the \square of the Diagonals AC and BD is equal to the two Rectangles of the opposite sides AB into CD , and AD into BC .

Demonstration.

Having drawn AE so that the Angle BAE shall be equal to the Angle CAD , the Triangles thereby formed (for they have the other Angles EBA and ACD in the same Segment equal, by virtue of Consect. 1. Prop. 33.) will be Equiangular one to another

and consequently (by Prop. 34.) as AC to AD and consequently (by Prop. 34.) as AC to AD so AB to BE . Wherefore by making $AC = a$ and $CD = e$, and $AB = b$, BE will be $= e$.

In like manner when in the $\Delta \Delta BAC$ and EAD , the respective Angles are equal (*viz.* adding the common part EAF to BAE and CAD , equal by Contr.) and besides the angles BCA and EDA in the same Segment are also equal; these Triangles will also be Equiangular, and AD will be to DE as AC to CB ; wherefore by putting, as before, a for AC , and oa for CB , and c for AD , DE will $= oc$. Therefore the whole $BD = eb + oc$. The Rectangle therefore of AC into BD will $= eba + oca =$; the Rectangle of AB into $CD = eba + \square$ of AD into $BC = oac$. Q. E. D.

SCHOLIUM

IN Squares and Rectangles (N. 2.) the thing is self-evident: For in Squares if the side be a , the Diagonals AC and BD will be $\sqrt{2aa}$, and so their Rectangle $= 2aa$ will be manifestly equal to the two Rectangles of the opposite sides. In Oblongs, if the two opposite sides are a and the others b , the Diagonals will be $\sqrt{aa + bb}$, and their Rectangle $aa + bb$ manifestly equal to the two Rectangles of the opposite Sides.

Proposition XLIX.

THE side (AB) of an Equilateral Triangle (ABC , Fig. 92. N. 1.) inscribed in a (α) Circle, is in Power triple of the Radius (AD) i. e. of the \square of AD .

Demonstration.

Make AD or $FD = a$, and so its Square aa . Since Therefore, having drawn DF thro' the middle of AB , or the middle of the Arch AFB let DE be $= \frac{1}{2} a$; for the angles at E are right ones, by *Consect. 5. Definit. 8.* and the Hypothenuses AD , AF , are equal, by *Schol. of Definition 15.* but the side AE is common. Therefore the other Sides FE and ED are equal by, by *Consect. 3. Prop. 43.* and the \square of the latter is $\frac{1}{4} aa$, which subtracted from aa leaves $\frac{3}{4} aa$ for the \square of AE . Therefore the line AE is $\sqrt{\frac{3}{4} aa}$, and consequently $AB = 2 \sqrt{\frac{3}{4} aa}$, i. e. $\sqrt{3 aa}$, i. e. $\sqrt{3 aa}$: therefore $\square AB = 3 aa$. Q. E. D.

CONSECTARYS.

I. IF the Radius of a Circle be $= a$, the side of an Incribed Regular Triangle will be $\sqrt{3 aa}$, e. g. if AD be 10, AB will be $\sqrt{300}$; and if AD be 10, 000, 000, AB will be $\sqrt{300, 000, 000, 000, 000}$, i. e. 17320508, and the Perpendicular DE 5000, 000.

II. Hence it is evident, that in the genesis of a *Tetraedrum* proposed in *Def. 22*, that the elevation CE (*Fig. 44, N. 1.*) is to the remaining part of the Diameter of the Sphere CF as 2 to 1; for making the Radius $CB = a$ and its $\square aa$, the \square of AB or BE will $= 3 aa$, by the present Proposition. Therefore the \square of CB being subtracted from the \square of BD or BE , there remains the \square of $CE = 2 aa$. But since CE , CB , CF , are continual Proportionals, by *N. 3. (a) Eucl. 12 Schol. 2. Prop. 34.* CE will be to CF as the \square lib. 12. of CE to the Square of CB , by vertue of *Prop. 35. i. e. as 2 to 1.*

SCHOLIUM.

Hence you have the *Euclidean* way of generating (a) a *Tetraedrum*, and inscribing it in a given Sphere, when he bids you divide the Diameter EF of a given Sphere so that EC shall be 2 and CF 1, and then at E to erect the Perpendicular CA , and by means thereof to describe the Circle ABD , and to inscribe therein an Equilateral Triangle, &c.

Proposition

Proposition L.

THE Side (AB) of a Regular Tetragon (or Square) ($ABCD$, Fig. 92. N. 2.) is double in Power of the Radius (AD).

Demonstration.

For having drawn the Diameter AC and BD , the Triangle AOB is Right-angled, and consequently, by the *Pythagorick Theorem*, if the \square of AO and BO be made equal to aa , then will the \square of $AB=2aa$, Q. E. D.

CONSECTARY.

Therefore when the Radius of the Circle AO is made $=a$, the side of the \square AB will $=\sqrt{2aa}$, e. g. if AO be 10, AB will be $\sqrt{200}$; and if AO be 10, 000, 000, AB will be $\sqrt{200, 000, 000, 000, 000}$, i. e. 14142136.

Proposition LI.

THE side AB of a Regular Pentagon (α) ($ABCDE$) (Fig. 93. N. 1.) is equal in Power to the side of an Hexagon and Decagon inscribed in the same Circle, i. e. the \square of AB is equal to the Squares AF and AO taken together.

Demonstration.

Make $AO=a$ and $AF=b$, $AB=x$:
 (a) Eucl. Prop. 13. lib. 13. We are to demonstrate that $xx=aa+bb$:
 (a) Eucl. Prop. 10. lib. 13. which may be done by finding the side AB by the parts BH and HA , after the following way:
 First of all the angle AOB is 72° , and the others in that Triangle at A and B 54° . But BGG is also 54° , as subtending the Decagonal Arch BF of 36° , and also one half of it FG of 18° . Therefore the $\triangle ABO$ and HBO are Equiangular, and you'll have

As

As AB to BO so BO to BH

$$x - a - a - \frac{aa}{x}$$

Secondly, in the Triangle BFA the Angles at B and A are equal by N. 3. *Consect.* 5. *Def.* 8. and by vertue of the same also the Angles at F and A in the $\triangle FHA$ are so too. Wherefore the $\triangle BFA$ and FHA are Equiangular, and you'll have

As BA to AF so AF to AH

$$x \text{ to } b - b - \frac{bb}{x}$$

Therefore the whole line AB (because the part AH is found $= \frac{bb}{x}$ and $BH = \frac{aa}{x}$) will be $\frac{aa + bb}{x}$, which was first made $= x$; so that now $\frac{aa + bb}{x} = x$, and multiplying both sides by x , $aa + bb = xx$. Q.E.D.

CONSECTARY I.

Therefore if the Radius of a Circle be (a) the side of a Pentagon AB will be $\sqrt{aa \times bb}$.

CONSECTARY II.

Therefore the $\square AI = \frac{aa + bb}{4}$ and $\square OI = \square OA - \square AI = aa - \frac{aa + bb}{4}$ i.e. $\frac{3aa - bb}{4}$. Therefore $OI = \sqrt{\frac{3aa - bb}{4}}$.

Which yet may be exprest otherwise, viz. $OI = \frac{a + b}{2}$

Demonstration.

Make (a) OA or OF (N. 2.) as before $= a$, $AF = b$, and FI now $= x$; then will $OI = a - x$ and having drawn the Arch FK at the Interval AF , so that AK may be equal to this, and $FI =$

(a) *Eucl. Prop.*
I. lib. 14.

$IK=x$; then will the angle $IKA=F72^\circ$. Therefore the angle $AKO=108$; and since KOA is 36° , KAO will be also 36° , and so $KA=KO=AF=b$. Wherefore OI is $=b+x$, which was above $a-x$. Therefore $2OI=a-x+b+x$, i. e. $a+b$. Therefore $OI=\frac{a+b}{2}$.

CONSECTARY III.

Therefore the difference between the Perpendicular of the Triangle DE (Fig. 92 and 93. N. 1.) and the Perpendicular of the Pentagon OI is $=\frac{1}{2}b$, by vertue of *Consect. 2.* of this and of the Demonstrat. of *Prop. 49.*

CONSECTARY IV.

Hence is also evident, by the present Proposition, that which in *Fabri's Genesis* of an *Icosaedr. Def. 22.* we said, viz. that (See Fig. 46.) Ba is equal to the side of a Pentagon BA , because, viz. Fa is $=$ to the Semidiameter OB , and BF is the side of a Decagon.

Proposition LII.

THE side of an Hexagon is in Power equal to the Radius, as being itself equal to it by N. I. Schol. Def. 15.

Proposition LIII.

THE side of a Regular Octagon ($ABCD$, &c. Fig. 94.) is equal in Power to half the side of the Square, and the difference (PB) of that half side from the Radius, taken together.

Demonstration.

For that the \square of AB is $=$ to the \square of $AP + \square BP$, is evident from the *Pythag. Theor.* But that PO is $=PA$ half the side of the Square, is evident from the equality of the Angles PAO and POA , since each is a half right one or 45° . Wherefore

tagon AF.) Wherefore the $\triangle ABC$ and ADC are Equiangular, and

AD to AC $\{$ as AC $\}$ to AB. Therefore the whole
i. e. BD $\{$ *i. e.* BD $\}$ line AD is divided in mean and extreme Reason. But BD is also divided in the same Reason by Hyp. Wherefore

As AD to DB and DB to BA,
 So DB to DE and DE to EB.

Therefore DB is in the same Proportion to DE as DB to BA. Therefore DE is $=BA$, and the Power of the one to the Power of the other. Q. E. D.

CONSECTARYS.

Therefore, if the Radius of the side of the Hexagon is a the side of the Decagon will be $\sqrt{\frac{5}{4}aa - \frac{1}{2}a}$, by Schol. 2.
 Prop. 27. *e. g.* if the Radius be 10, the side of the Decagon will be $\sqrt{125 - 5}$, and if the Radius be put 10 000 000, the side of the Decagon will be $=\sqrt{125\ 000\ 000\ 000\ 000\ 000 - 5000\ 000}$, viz. by adding the Square of the Radius and the Square of half the Radius into one Sum; whence you'll have the side of the Decagon $=6180340$; the half whereof 3090170 gives the difference between the Perpendiculars of the Triangle and the Pentagon, by Conf. 3. Prop. 51.

II. The side therefore of the Pentagon is by Prop. 51. $\sqrt{\frac{5}{2}aa - \sqrt{\frac{5}{4}a^4}}$; for the Square of the Hexagon is aa or $\frac{2}{2}aa$, the \square of the Decagon $\frac{3}{2}aa - \sqrt{\frac{5}{4}a^4}$: the Root extracted out of the Sum of these is the side of the Pentagon, viz. $\sqrt{\frac{5}{2}aa - \sqrt{\frac{5}{4}a^4}}$
e. g. if the Radius be 10, the side of the Pentagon will be $\sqrt{250 - \sqrt{125000}}$, and if the Radius be put 10 000 000, since the side of the Hexagon is equal to it, and the side of the Decagon 6180340, their Squares being added into one Sum, the Root extracted out of that Sum will give the side of the Pentagon, 1755704 nearly; and the sides being collected into one

one sum, the half of it 8090170 will give the Perpendicular in the Pentagon OI , by *Consect. 2. Prop. 51.*

SCHOLIUM I.

TO illustrate what we have deduced in the *Consectarys* of *Prop. 51*, you may take the following Notes. If a be put $= 10$ or $\frac{1000}{100}$, the side of the Decagon will be $= \sqrt{125} = 5, i.e.$ $\frac{618}{100}$ nearly $= b$; therefore the $\square aa = \frac{1000000}{10000}$ and the $\square bb = \frac{381927}{10000}$: therefore $aa + bb$ or the $\square AB = \frac{1381924}{10000}$, the Perpendicular $OI = \frac{a+b}{2} = \frac{1618}{100}$ divided by 2, that is, $\frac{809}{100}$. Now

the \square of AI is $\frac{1}{4}$ of the $\square AB = \frac{345481}{10000}$ the $\square OI = \frac{aa + 2ab + bb}{4}$ $= \frac{64481}{10000}$. Now if you add the $\square AI$ and the $\square OI$, the sum will be $= \square AO = \frac{2aa + 2ab + 2bb}{4}$, *i.e.* $\frac{aa + 2ab + bb}{2} = \frac{99}{1} | \frac{996}{0000}$, or near 100. Thus likewise, since the Perpendicular above found OI , in *Consect. 1.* may be also determined by $\sqrt{3aa - bb}$, since aa is $= \frac{1000000}{10000}$, and $3aa - bb = \frac{2618076}{10000}$, subtracting from it $bb = \frac{381924}{10000}$ the Remainder will be $\frac{2618076}{10000}$, and this being divided by 4, you'll have the $\square OI = \frac{654519}{10000}$. and the Root of it extracted $\frac{809}{100}$ nearly; so that those two different quantities in *Consect. 1.* will rightly express the same Perpendicular OI .

SCHOLIUM II.

NOW therefore as we have Practical Rules to determine Arithmetically the sides of the Pentagon and Decagon, so also they may be found Geometrically by what we have demonstrated. For if the Semidiameter CB (*Fig. 96. N. 1.*) be divided into 2 parts, EC will $= \frac{1}{2}a$; and erecting perpendicularly the Radius $CD = a$ DE will $= \sqrt{\frac{5}{4}aa}$. Moreover if you cut off EF equal to it, FC will be $= \sqrt{\frac{5}{4}aa} - \frac{1}{2}a =$ to the side of the Decagon, by *Consect. 1.* Having therefore drawn DF , which is equal in Power to the Radius or Side of the Hexagon DC and the side of the Decagon FC together, by the *Pythag. Theorem*

it will be the side of the Pentagon sought. Much to the same purpose is also this other new Construction of the same Problem, wherein BG (Numb. 2.) is the side of the Hexagon BD the side of the Square, to which GF is made equal, so that FC is that side of the Decagon, and DF of the Pentagon; which we thus demonstrate after our way: Having bisected GH the side of an Equil. Triangle, the Square of GE will be $\frac{3}{4} a a$, by Prop. 48. which being subtracted from the Square of GF $= 2 a a$, viz. $\frac{8}{4} a a$, by Prop. 49. there will remain for the Square of EF $\frac{5}{4} a a$, and for the line EF $\sqrt{\frac{5}{4} a a}$, and for FC $\sqrt{\frac{5}{4} a a} - \frac{1}{2} a$, which is the side of the Decagon, as DF of the Pentagon, after the same way as before.

Proposition LV.

THE side of a Quindecagon (or 15 sided Figure) is equal in Power to the half Difference between the side of the Equil. Triangle and the side of the Pentagon, & moreover to the Difference of the Perpendiculars let fall on both sides taken together.

Demonstration.

For if AB (Fig. 97.) be the side of an Inscribed Triangle, and DE the side of a Pentagon parallel to it; AD will be the side of the Quindecagon to be inscribed, by Consect. 4. Def. 15. But this side AD in the little Right-angled Triangle, is equal in Power to the side AH (which is the half Difference between AB and DE) and the side HD (which is the difference between the Perpendiculars CF and CG) taken together by the Pythag. Theor. Q. E. D.

CON-

CONSECTARY.

Hence if we call the Side AB of the Equil. $\triangle c$, and make the side of the Pentagon $DE=d$, AH will $\frac{c-d}{2}$

HD is $\frac{1}{2}b$, by *Consect. 3. of Prop. 51.* Since therefore the $\triangle AH$ is $\frac{cc-2cd+dd}{4}$ and the $\triangle HD$ is $\frac{cd}{2}$ the $\triangle AD$ will

$$\frac{cc-2cd+dd}{4}$$

Therefore the side of the Quindecagon $= \sqrt{\frac{cc-2cd+dd}{4}}$

that is, Collecting the Square of the half difference of the sides of the Triangle and Pentagon, and the Square of the difference of the Perpendiculars into one Sum, and then Extracting the Square Root of that Sum, you'll have the side of the Quindecagon sought. *E. g.* if the Radius CI be made 10000000 the difference of the sides of the Triangle 17320508, and of the side of the Pentagon 11757704 will be 5564804, and the half of this 2782402; but the difference of the Perpendicular CH from the Perpendicular CG , is 3090170.

The Squares therefore of these Two last Numbers being Collected into one Sum, and the Root Extracted will give the side of the Quindecagon 4158234 nearly.

SCHOLIUM.

Here we will shew the Excellent use of these last Propositions in making the Tables of Signs. For having found above, supposing the Radius of 10000000 parts, the sides of the chief Regular Figures, if they are Bisected, you will have so many Primary Sines; viz. from the side of the Triangle the side of 60 Degrees 8660754, from the Side of the Square the Sine of 45° 7071068; from the Side of the Pentagon, the Sine of 36° 5877853; from the Side of the Hexagon, the Sine of 30° 5000000; from the Side of the Octagon, the Sine of $22^\circ 30'$ 3826843; from the Side

of the Decagon the sine of $18^\circ = 3090170$; from the side of the quindecagon lastly the sine of $12^\circ = 2079117$. From these seven primary sines you may find afterwards the rest, and consequently all the Tangents and Secants according to the Rule we have deduc'd; *n. 3. Schol. 5. Prop. 34.* and which *Pb. Lansbergius* illustrates in a prolix Example in his *Geom. of Triangles Lib. 2. p. 7.* and the following. But after what way, having found these greater numbers of sines, Tangents, &c. Logarithms have been of late accommodated to them, remains now to be shewn, which in brief is thus; *viz.* the Logarithms of sines, &c. might immediately be had from the Logarithms of vulgar numbers, if the tables of vulgar numbers were extended so far, as to contain such large numbers; and thus the sine *e. g.* of $0^\circ 34'$ which is 98900 the Logarithm in the Chiliads of *Vlacquius* is 49951962916. But because the other sines which are greater than this are not to be found among vulgar numbers (for they ascend not beyond 100000, others only reaching to 10000 or 20000) there is a way found of finding the Logarithms of greater numbers, than what are contained in the Tables. *E g.* If the Logarithm of the sine of 45° which is 7071068 is to be found, now this whole number is not to be found in any vulgar Tables, yet its first four notes 7071 are to be found in the vulgar Tables of *Strauchius* with the correspondent Logarithm 3.8494808, and the five first 70710 in the Tables of *Vlacquius* with the Log. 4.8494808372. One of these Logarithms, *e g.* the latter, is taken out, only by augmenting the Characteristick with so many units, as there remain notes out of the number proposed, which are not found in the Tables, so that the Log. taken thus out will be 6.8494808372. Then multiply the remaining notes of the proposed number by the difference of this Logarithm from the next following, (which for that purpose is every where added in the *Vlacquian* Chiliads, and is in this case 61419) and from the Product 4176492 cast away as many notes as adhere to the proposed number beyond the tabular ones, in this case 2; for of the remainder 41764, if they are added to the Logarithm before taken out, there will come the Logarithm required 6.8494850136, *viz.* according to the Tables of *Vlacquius*, wherein for the Log. of 10 you have 10, 000, 000, 000;

000; but according to those of *Strauchius* which have for the Logarithm of 10 only 10, 000, 000, you must cut off the three last notes, that the Logarithm of the given sine may be 6. 8494.850; as is found in the *Strauchian* and other tables of sines, except that instead of the Characteristick 6 there precedes the Characteristick 9, whereof we will add this reason: If the Characteristicks had been kept, as they were found by the rule just now given, the Logarithm of the whole sine (which is in the *Strauchian* Tables 10, 000, 000) would have come out 70, 000, 000, incongruous enough in Trigonometrical Operations. Wherefore that Log. of the whole sine might begin from 1, for the easiness of Multiplication and Division they have assumed 100, 000, 000; the Characteristick being augmented by three, wherewith it was consequently necessary to augment also all the antecedent ones; and hence *e. g.* the Logarithm of the least sine 2909 begins from the Characteristick 6, which otherwise according to the Tables of vulgar numbers would have been 3.

Having found after this way the Logarithms of all the sines (altho' here also if you have found the Logarithms of the signs of 45° and moreover the Logarithm of 30, the Logarithms of all the rest may be compendiously found by addition and subtraction from a new principle which now we shall omit) the Logarithms of the Tangents and Secants may easily be found also, only by working, but now Logarithmically, according to the Rules of *Schol. 5. Prop. 34. n. 5. and 6.*

Proposition LVI.

(*a*) *Euel.*
13. *lib. 13.*
THE side of a Tetraëdron (*a*) or equal Pyramid is in power to the Diameter of a circumscribed Sphere, as 2 to 3.

Demonstration.

For because by the genesis of the Tetraëdron *Def. 22* (see its *Fig. 44 n. 1.*) and *Schol. Prop. 49.* OC is $\frac{1}{3}$ of the semidiameter OB, which we will call *a* the \square of CB will be $\frac{8}{9}aa$ by the *Pythag. Theor.* and so the power (or Sq.) of the side of the Tetraëdron $\frac{24}{9}aa$ by *Prop. 49.* but the power

er of the Diam. $2a$ or $\frac{6}{3}a$ is $\frac{36}{9}aa$. Therefore the power of the side of the *Tetraëdram* is to the power of the Diam. as 24 to 36. *i. e.* (dividing each side by 12) as 2 to 3. Q. E. D.

Or more short.

The \square of CB is $\equiv 2$ by *Schol* of *Prop.* 49. and the \square of EC $\equiv 4$. Therefore the \square EB $\equiv 6$. But the \square EF is $\equiv 9$. Therefore the \square of EB is to the \square of EF as 6 to 9, *i. e.* as 2 to 3. Q. E. D.

CONSECTARY.

Therefore if the Diam. EF be made $\equiv a$, the side EB will be $\equiv \sqrt{\frac{2}{3}aa}$.

Proposition LVII.

THE side of the *Octaëdram* (a) is in power one half of the Diameter of the circumscribed Sphere. (a) *Eucl.* 14. lib. 13.

Demonstration.

For since by the genesis of the *Octaëdram* Def 22. (see Fig. 44. n. 2.) CA, CB, CF, &c. are so many radii of great circles, if for Radius you put a , the square of AF will be $\equiv 2aa$ by the *Pythag. Theor.* But the square of the Diam. FG $\equiv 2a$ is $4aa$. Therefore the power of the side is to the power of the Diam as 2 to 4, *i. e.* as 1 to 2. Q. E. D.

More short.

Because AF is also the side of a square inscribed in the greatest circle by the gen. of the *Octaëdram*; the \square of AF will be by *Prop.* 50. to the \square of FC as 2 to 1: Therefore to the square of FG as 2 to 4, by *Prop.* 35. Q. E. D.

CONSECTARY.

Therefore if the Diam. of the sphere be made (a) the side of the Octaëdrum AF will be $\sqrt{\frac{1}{2}aa}$.

Proposition LVIII.

(α) Eucl. 15. lib. 13. **T**HE side of the Hexaëdrum or Cube (a) is in Power subtriple of the diameter of the circumscribed sphere.

Demonstration.

Making a the side of the inscribed cube GF or FE (Fig. 98.) the square of the diagonal GE of the base of the cube will be $2aa$ by the *Pythag. Theor.* and by the same Reason the square of the diam. of the cube and the circumscribed sphere GD will be \equiv to the square of GE $\dagger \square DE \equiv 3aa$. Q. E. D.

CONSECTARYS.

I. **T**herefore if the diameter of the sphere be made $\equiv a$ the side of the cube AB will be $\sqrt{\frac{1}{3}aa}$.

II. The diameter of the sphere is equal in power to the side of the Tetraëdrum and cube taken together. For if the power of the diam. of the sphere be made aa the power of the side of the Tetraëdrum will be $\frac{2}{3}aa$ by *Consect. Prop. 56.* and the power of the side of the cube $\frac{1}{3}aa$ by the *prel. Consect. 1.* Wherefore these two powers jointly make aa . Q. E. D.

Proposition LIX.

(α) Eucl. Consect. 1. Prop. 17. lib. 13. **T**HE side of the Dodesaëdrum (a) is equal in power to the greater part of the side of the cube divided in mean and extreme reason.

Demonstration.

For if to the side of the cube AB (*vid. Fig. 45. n. 1.*) and to its upper base ABCD you conceive to be accommodated or fitted a regular Pentagon according to the genesis of a *Dodecaëdron* laid down in *Def. 22.* and at the interval Be you make the arch ef, the $\triangle ABe$ and $\triangle Aef$ will be equiangular; (for the angles at A and B being 36° , and AeB 108° , having drawn ef, the angles Bef and Bfe are each 72° ; therefore Aef the remaining angle will be 36°) wherefore as AB to Be (*i. e.* Bf) so Ae (*i. e.* Be or Bf) to Af. Therefore the side of the cube AB is divided in mean and extream reason in f, and Be the side of the *Dodecaëdron* is \equiv to the greater part Bf. Q. E. D.

SCHOLIUM.

Hence would arise a new method of dividing a given line in mean and extream reason, *viz.* if you apply to the given line a part of the equilateral Pentagon by means of the angles A and B 36° , and at the interval Be you cut off Bf. This angle may be had geometrically, if another regular Pentagon be inscribed in a circle, and having drawn also a like subtense, if the angles at the subtense are made at A and B equal, by *Eucl. 23. lib. 1.*

Proposition LX.

THE side of an *Icosaëdron* (a) is equal in power to the side of a Pentagon in a circle containing only five sides of the *Icosaëdron*; and the semi diameter of this circle is in power subquintuple of the Diam. of the sphere of the circumscribed *Icosaëdron*.

(a) *Eucl. Prop. 16. Coroll. lib. 13.*

Demonstration.

Both these are evident from the genesis of the *Icosaëdron* in *Def. 22.* The first immediately hence, because all the other sides

sides of the triangles (*Fig. 99.*) $Aa, Ba, &c.$ are made equal to the side of the Pentagon AB by *Consect. 4. Prop. 51.* The latter from this inference; if for OA the radius of the circle you put a (since the side of the Pentagon, which here is also the side of the *Icosaëdron*, it will be equal in power to the radius and side of the Decagon taken together by the aforesaid *Prop.*) the altitude OG will be the side of the Decagon $\equiv \sqrt[4]{aa} - \frac{1}{2}a$ by *Consect. 1. Prop. 54.* to which the equal inferior part oH being added, and the intermediate altitude $Oo \equiv a$, you'll have the whole diameter of the circumscribed sphere $GH \equiv a + 2\sqrt[4]{aa} - \frac{1}{2}a$ i. e. $2\sqrt[4]{aa}$ i. e. $\sqrt[20]{aa}$ i. e. $\sqrt[5]{5aa}$ and so the square of the diameter of the sphere will be $5aa$: Therefore the square of the diameter of the sphere is to the square of the semi-diam. of the circle containing the five sides of the *Icosaëdron* as 5 to 1. Q. E. D.

S C H O L I U M.

IT is also evident that a sphere described on the diameter GH will pass thro' the other angles of this *Icosaëdron*; for assuming the center between O and o the radius FG will be $\equiv \sqrt[4]{aa}$. But FA is also $\equiv \sqrt[4]{aa}$; for the \square of FO is $\equiv \frac{1}{4}aa$, and the \square $AO \equiv aa$: Therefore the sum is $\equiv \frac{5}{4}aa \equiv \square FA$. Q. E. D.

CONSECTARY I.

Therefore, if the radius of the circle $ABCDE$ remain a , you'll have the altitude $OG \sqrt[4]{aa} - \frac{1}{2}a$, and the side of the *Icosaëdron* $\sqrt[2]{aa} - \sqrt[4]{a^4}$, by *Consect. 1. and 2. Prop. 54.* and the diam of the circumscribed Sphere $2\sqrt[4]{aa}$, as is evident from the Demonstration.

CON-

CONSECTARY II.

Being a general one of the five last Propositions.

(a) *Eucl. Prop. 18. and Iosſ. lib. 13.* IF AB (*Fig. 100*) be the diameter of a sphere (a) divided in D so that AD shall be $\frac{1}{3}$ AB, then (having erected the perpendicular DF) BF will be the side of the *Tetraëdram* by *Prop. 56.* and AF the side of the *Hexaëdram* by *Prop. 58. Conf. 2.* and BE or AE (erecting from the center the perpendicular CE) will be the side of the *Octaëdram* by *Prop. 57.* Now if AF be cut in mean and extreme reason in O, you'll have AO the side of the *Dodecaëdram* by *Prop. 59.* Lastly, if you erect BG double of CB, HI will be double of CI, and the \square of HI $\equiv 4 \square$ of CI; consequently the \square CH or CB $\equiv 5 \square$ CI. Therefore the \square of AB (double of CH) is also \equiv to $5 \square$ of HI (which is double of CI) therefore HI is the radius of the circle circumscribing the Pentagon of the *Icosaëdram*, and IB the side of the *Decagon* inscribed in the same circle, and HB the side of the *Pentagon*, and also the side of the *Icosaëdram*, by *Prop. 60.*

The End of the first Book.

THE

THE SECOND BOOK

SECTION I.

Containing

DEFINITIONS.

Definition I.

IF a Cone ABC (*Fig. 101.*) be conceived to be cut by a plane at right angles to the side of the cone, e. g. BA; the Plane EFGHE arising by this section, and terminated on the external surface of the cone by the curve line HEG, &c. was anciently by *Euclid*, *Archimedes*, &c. called the *Conick Section*; and if the sides of the cone AB and BC made a right angle at B, as *n. 1.* the section was particularly called the *Section of a right-angled Cone*; but if it made an obtuse angle, as *n. 2.* it was called the *Section of an obtuse-angled Cone*; if, lastly, it made an acute one, as *num. 3.* it was called (3) the *Section of an acute-angled Cone*.

Definition II.

BUT afterwards their Successors, particularly *Apollonius Pergæus*, found from the properties of these Curves, which their Predecessors had happily discovered, that the same (all of them) might be generated in one and the same cone whether right-angled, obtuse-angled, or acute-angled, if the section EF (*Fig. 102.*) is made in the first case parallel to the

the opposite side BC ; in the second case, if it meet that side produced upwards ; for the third, when it meets downwards with the diameter of the base AC produced to D. And to give new names (for the old ones would do no more now) to these Sections, to distinguish them one from another, nominating them from their Properties hereafter demonstrated, they called the first a *Parabola*, the second an *Hyperbola*, the third an *Ellipsis*.

Definition III.

BUT it is evident, that only the plane making the section of the second case, being according to the line FED produced or carried on, (Fig. 103.) will fall upon the vertical Cone aBc comprehended under the sides AB, CB, &c. continued onwards, and there produce another Section opposite to the former ; whence these, viz. GEHG and gehg are called *opposite Sections*.

Definition IV.

BESIDES these names of the sections, there are several others made use of to denote various lines drawn and considered both within and without those sections, the chief whereof we shall here explain. And first of all, in general the line EF so let fall thro' the middle of the section from its top E (which is called the *Vertex* of the section) to the diameter of the base of the Cone AC (produced if occasion be) that it shall bisect the line GH and all others parallel to it, is called the *Diameter* of that *Section* ; and particularly it is called the *Axis* of the *Section* if it cuts them at right angles or perpendicularly ; as also they name those lines GH, KN, &c. which are cut indifferently by the diameters, but at right angles by the Axis, those, I say, they call *Ordinates*, or *Ordinate Applicates*, and their halves, FG, IK, &c. *Semiordinates*, (or some also call the latter *Ordinates*, and the former *double Ordinates*) and the parts of the Ax or Diameter EF, EI, &c. are called *Abscissas* (by some *intercepted axes* and *diameters*)

Definition V.

PArticularly in the hyperbola they call the continuation of the ax or diameter ED 'till it meet the opposite side eB, i. e. to the vertex of the opposite section, the *Latus transversum* of the Hyperbola, to which there answers in the Ellipsis the axis or longest diameter, and so by latter Authors is called by the same name, but by Apollonius the *transverse Ax* or the *transverse Diameter*, as also the shortest ax or diameter is called the *Conjugate*, and its middle point O is called the *Center of the Section* or of the *opposite Sections*.

Definition VI.

They called also a certain line EL (Fig. 101.) by the name of *Latus Rectum*, which is particularly to be found in all the sections, as we shall hereafter shew: And because this *Latus Rectum* is a sort of a Rule or Measure, according to which the squares or powers of the ordinates used to be estimated or valued (as we will shew in its proper place) therefore the Ancients used to call it by a Periphrasis *Linea secundum quam possunt Ordinatum applicatae*, or the measure of the powers of the Ordinates; by some latter Authors it is called the *Parameter*. Now a mean proportional PQ found between this *Latus Rectum* and the *Latus Transversum* (Fig. 104 n. 1. and 2) (see also hereafter *Consect. 2. Prop. 8.*) and drawn thro' the centre O parallel to the Ordinates is called the *second Axis* or *Diameter*, or the *Conjugate* of the Hyperbola.

Definition .VII.

NOW if we conceive the diameter or conjugate ax PQ brought down to the Hyperbola so that its middle point O shall touch its vertex in E, and from the center O you draw the right lines OR, OS, thro' the ends of this tangent line p and q, these are the lines which Apollonius, *Prop. 1. lib. 2.* demonstrates, that tho' by being continued, they always approach nearer and nearer to the curve GEH, and come so much

much the nearer by how much the farther they are continued, yet they will never concur with it or touch it, for which reason they are called Asymptotes or non-coincident lines; and by some the *Intactæ*. Which non-coincidency appears most manifestly where the hyperbolical section of the cone is made parallel to the triangular section thro' the axis of the cone ABC (*n.* 3.) along the line *e. f.* parallel to the ax BF. For if we conceive the hyperbola *geb* to move forwards always parallel to it self, according to the direction of the equal and parallel lines *gG, fF,* and *bH,* till it stands in the position GEH; it is manifest that the curve line GEH is distant on both sides from the right lines BC, BA, the length of the versed line of the equal arches *bC* and *gA* in the circumference of the circular base, while in the mean time it is evident that they approach nearer and nearer to them. So that hence there flow the following

CONSECTARYS.

I. IN this case the sides of the cone are the Asymptotes of the hyperbola, while it is manifest, that the point B is its centre, and EB half the transverse diameter; which appears from *n.* 1. and 2. of the *pres. Fig.* for the section *ef* being made parallel to the the ax of the cone DF by *def.* 5. *d e* (which in the case *n.* 3. would coincide with *dq*) is the transverse diameter, but the triangles *dpq* and *OpE* are equiangular, and consequently as *pE* is to $\frac{1}{2}pq$, so is OE to $\frac{1}{2}dq$.

II. The lines AG and HC (*num.* 3.) are equal, as being the versed sines of equal arches; and in like manner (*n.* 1. and 2.) RG and HS are equal, since FR and FS as well as Ep and Eq are so also (for

as OE to Ep, so OF to FR } and the semiordinates FG and
 —Eq —FS }

FH are also equal.

III. Consequently \square of RG into GS and of HS into HR are equal, &c. all which hereafter we will more universally demonstrate.

Definition VIII.

(a) Archim.
de Conoid. &
Spher. Def. 1.

IF a parabolick plane (a) HEGFH (Fig. 105. n. 1.) together with a triangle HEG inscribed in it, and a rectangle HL circumscribed about it, be conceived to be moved round about the ax EF on the point F; it will be evident that by the triangle there will be generated a cone, by the rectangle a cylinder, and by the parabola a parabolick solid, which with the comprehended cone, and the comprehending cylinder, will have the common base HIGK and the same altitude EF, and was by *Archimedes* named a *Parabolick Conoid*.

Definition IX.

(a) Archim.
de Conoid. &
Spher. Def. 3.

IF moreover an (a) hyperbolick plane HEGFH (n. 2.) with the inscribed triangle HEG, and another circumscribed one ROS made by the Asymptotes OR, OS, be conceived to be turned about the common ax OEF on the point F; it will be evident that there will be described by the inscribed triangle a cone comprehended within side, and by the hyperbola an *Hyperbolical Conoid* upon the same base HIGK and of the same height EF; and by the \triangle ROS another cone which *Archimedes* calls the comprehending cone, whose base is RTSV, and its altitude composed of the axis of the hyperbola EF and half the transverse ax OE, (which *Archimedes* called the additament of the ax of the hyperbola) and which we may commodiously divide into two parts, viz into the cone OPMQL, whose base has for its diameter the conjugate ax PQ, and its altitude equal to half the transverse ax; and into a *Curti-cone* or detruncated cone terminated by the two bases PMQL and RTSV, but answering in altitude to the conoid and inscribed cone: From which, as comprehending it, if you take away the included conoid, there will remain the hollow curticone terminated below by the *Annulus* or ring RGIVHSKT and above by the circular base PMQL, and generated in the circumvolution by the intermediate lines EP, GR, &c. or the mixtilinear plane EGRP. Now if we suppose instead of

this

this comprehending cone a circumscribed cylinder on the same base and of the same altitude with the conoid and included cone, you'll have every thing like as in *Def.* 8.

CONSECTARYS.

NOW if we suppose the 1. case of *Def.* 9. to be expressed by the *Fig.* of *Def.* 7. *n.* 3. and conceive the present figure brought thence to be turned round about the axis BEF (*Fig.* 106.) we may deduce these following things in the room of Consectarys for the foundation of our future demonstrations.

I. The lines EQ, RS, HC, &c. of the mixtilinear space comprehended between the hyperbola and the Asymptotes (*viz.* the excess of the ordinates) altho' they are unequal, and by descending always grow less, yet in this circumvolution they will describe equal circular spaces, *viz.* EQ a whole circle, (or circular plane) but RS and HC, &c. circular *Annuli* or rings all of the same bigness; which will thus appear to any one who compares this figure with the former: Since the spaces generated by the lines EQ, FC, &c. are as the squares of those lines, and the \square of Fb or FC exceeds the square of fb or FH by the excess of the square Ff or Ee or EQ, consequently the quantity generated by FC will exceed that generated by FH the excess of that generated by EQ; and also that generated by FH by the excess of that generated by HC; it is manifest that the circle generated by EQ will be equal to the annular space generated by HC; and the same will in like manner be evident of any spaces produced by RS.

II. Therefore the hollow detruncated cone generated by the space EHCQ according to *Def.* 9. will be equal to a cylinder generated by the rectangle FIQE; for all the indivisibles of the one, are equal to all the indivisibles of the other by *Consect.* 1.

Defi.

Definition X.

(a) *Archim.
de Conoid. &
Spher. D.f. 6.*

IF, lastly, (a) an elliptical plane be turned about either of the axes, viz. either the longest DE (*Fig. 107. n. 1*) or the shorter AB (*n. 2.*) there will be thence formed an elliptical solid, called by *Archimedes* a spheroid; which in the first case will be an oblong or erect one, in the other a flat or depressed one: And it is self evident, that if before this circumvolution of the ellipsis, there be inscribed in one of its halves a triangle, and also a rectangle circumscribed about it, having the same altitudes and bases with the semi ellipse, there will afterwards in the circumvolution be described by the triangle a cone, by the rectangle a cylinder, to which afterwards we will also compare the half spheroid; as also both the conoids with their inscribed and circumscribed cones and cylinders.

Definition XI.

IF upon the right line AE (*Fig. 18.*) you conceive a wheel or circle to rowl, until its point A, with which it touches the said line, come to touch it again in E; the circle will measure out the line AE equal to its periphery; but the point A by its motion will describe the curve line AFE, which is called a *Trochoid* or *Cycloid*; and the area which this curve with the subtense AE comprehends, is named the *Cycloidal Space*; and the circle by whose motion they are determined is called the *generating Circle*.

CONSECTARY.

IT is evident from the genesis of this curve that the describing point *a* will always be as much distant in the circle from the point of contact *d* or *c*, as the point A in the right line passed over AE, is from the same point of contact, i. e. if the point *d* is distant from A the fourth part of the line AE, the arch *da* will also be the fourth part of the circle considered in this second station; and the point *c* being distant from A half of the interval AE, the arch *ca* will be also half of the circle,

circle, and so the point *a* coincide in the curve with F: And when the point *e* is distant from E only an eighth part of the whole line AE, the arch *ea* will also be the eighth part of the whole circle.

Definition XII.

IF the right line BA (*num.* 1. 109.) one end at B remaining fixed, be moved round at the other end with an equal motion from A thro' C, D, E to A back again, and in the mean while, there be conceived another moveable point in it to move with an equal motion along the line BA from B to A, so that in the same moment wherein the moveable point A absolves one revolution, the other moveable point shall also have passed thro' its right lined way, coinciding with the point A returned to its first situation; this extremity A by its revolution will describe the circle ACDEA, and that other moveable point another curve B, 1, 2, 3, 4, &c. which with *Archimedes* we will call a *Helix* or *Spiral Line*, and the plane space comprehended under this spiral line and the right line BA in the first station is called a *Spiral space*. Now if we suppose, *e.g.* the right lined motion of the point moving along BA to be twice slower than in the former case, so that (*see num.* 2.) in the same time that the point A makes one whole Revolution, the other moveable point shall come to F, making half the way BA, and then at length shall concur or meet with the extremity, when that shall have performed the other revolution; and so there will be described a double spiral line, whose parts with *Archimedes* we will so distinguish, that as he calls the part of the right line BF, passed over in the first revolution, simply the *first line*, and the circle made by the right line BF the *first Circle*; so we will call that part of the curve which is described in that time or revolution B 1 3 6 9 12 the *first Helix* or the *first Spiral*, and the area comprehended under it the *first spiral space*: And, as the other part of the right line FA passed over in the other revolution is called the *second line*, and the circle marked out by the whole line BA the *second Circle*; so the curve described in the mean while 12, 15, 18, 24, may be called the *second spiral line*, and the space, compre-

comprehended under it the *second spiral space*, and so onwards
From these Definitions there flow the following

CONSECTARYS.

I. **T**HE lines B 12, B 11, B 10, &c. drawn out, and making equal angles to the first or second spiral (and after the same manner (α) B 12, B 10, B 8, &c. or B 12, B 9, B 6, &c.) are arithmetically proportional, as is evident.

(α) *Archim.*
Prop. 2. of
Spirals.

II. The lines drawn out to the first spiral as B 7, B 10, &c. are one among another as the arches of the circles intercepted between BA and the said lines (β) B 7, B 10, &c. which is also evident to any one who considers what we did suppose; for in the same time as the end A passes over seven parts of the circle, the other moveable point will also run over seven parts of the right line BA, &c.

III. Lastly, The right lines drawn from the initial point (γ) B to the second spiral e. g. B 19 and B 22 (*num. 2.*) will be one to another as the aforesaid arches together with the whole periphery added to both sides: for at the same time the extremity A runs thro' the whole circle or 12 parts and moreover 7 parts (*i. e.* in all 19 parts) in the same time the other moveable point passes through 12 parts of the right line BA (in this case divided into 24 parts) and moreover 7 parts, that is, in all 19; and so in the others.

(γ) *Archim.*
Prop. 15.

Definition XIII.

IF a right line BAF be conceived so to move within the right angles ADC, CDE, that on the one hand a certain point C fixed in one leg of the *Norma* or ruler may always glide along, and on the other hand a certain moveable point A may always run along the other side of the *Norma* (which complicated motion of the describing rule BAF, after what way it may be organically procured, may be seen by the

the 110th. Figure;) by the extreme point of the moveable line B there will be described a curve called by its Inventor *Nicomedes* the *first Conchoid*, whereof this is a property, that the right lines CB, Cb, drawn from its centre C to its *Ambitus* or curvity are not themselves, as in the circle, equal, but yet have all the parts, AB, ab, intercepted between the curve, and the directrix AE are equal; as is evident from its genesis.

Definition XIV.

IF, the diameters of a circle being AB and CD (*Fig. 111. n.* 1.) cutting one another at right angles, you take BE or Be and BF or Bf equal arches, and from E or e you draw the perpendiculars EG or Eg, and through these from D to F or f you draw the transverse lines DF or Df; the several points of intersection H, h, &c. decently connected together will exhibit the curve line Db, HbB (which may be continued also without the circle if you please, and) which is commonly attributed to *Diocles*, and called a *Cissoïd*.

Definition XV.

IF, having divided the right line AE (*Fig. 112.*) into the equal parts AB, BC, &c. from the points of the division A, B, C, &c. you draw the parallel lines Aa, Bb, Cc, &c. in geometrical progression (as e. g. let Aa be 1, Bb 4, Cc 16, Dd 64, &c. or Bb 10, Cc 100, Dd 1000, Ee 10000, &c.) and further bisecting AB, BC, &c. F, G, H, I, you let fall mean proportionals between the next Collaterals ff, Gg, Hh, Ii, &c. and continue to do so till the parallels are brought near to one another; the curve line drawn thro' the extremities of these lines af, bg, ch, &c. will be the logarithmical line of the moderns, whose properties and uses are very excellent.

S C H O L I U M.

AMong those uses, that is none of the least, from which this curve borrows its name, viz. in shewing the nature and invention of Logarithms. For, e. g. 1. If this line was accurately delineated in a large space, the parts AB, BC,

N

BC, &c. being taken so big, that they might be subdivided not only into 100 or 1000 but into 10000 or 100000 parts; making AB 100000 (and so A 00000) AC would be 200000, AD 300000, &c. while in the mean while there answer to these as primary Logarithms in arithmetical progression the geometrical proportional numbers, Aa 1, Bb 10, Cc 100, Dd 1000, Ee 10000, &c. Whence, 2. Its Logarithm may be assign'd to any given intermediate number, e.g. to the number 982, for having cut off this number from Dd by a geometrical scale on the line DM, if you draw Mn parallel to AD, and nN parallel to DM, it will give AN on the same scale, viz. the Logarithm sought, and reciprocally. But if, 3. it seem difficult to delineate a Figure so large, yet at least the clear conception of such a delineation evidently shews the arithmetical method, which those ingenious Men have made use of, who have made the tables of Logarithms with a great expence of Labour and pains, viz. by finding continual mean proportionals, arithmetical ones between any two Logarithms already known, and geometrical ones between two vulgar numbers answering to them, &c. by comparing what we have noted in *Schol. 2. Prop. 20. Lib. 1.* And we will note, 4. out of *Pardies*, that, since the Logarithms of numbers distant from one another by a decuple proportion, differ by the number 100000, having found the Logarithms of all the numbers from 1000 to 10000 you will at the same time have all the Logarithms of all the other numbers that are between 100 and 1000, between 10 and 100, and between 1 and 10, only changing the characteristic, and lessening it in the first case by unity, in the second by 2, in the third by 3; as e.g. if of the number 9, 900 you had found the Logarithm 359, 563, the Logarithm of the subdecuple number 990 would be (viz. subtracting from the former 100000) 299, 563. and the Logarithm again of this subdecuple of this 99 would be 199, 563, &c. Thus in the *Chiliads* of *Briggs* to the number

99000	Answ.	4,	99563,	51946
9900	—	3,	99563,	51946
990	—	2,	99563,	51946
99	lastly—	1,	99563,	51946.

But there will not arise such advantage for making Logarithms by this observation as it may at first sight seem to promise, because there are 9000 numbers between 1000 and 10000 whose Logarithms must be found also, and but 900 between 100 and 1000, and but 90 between 10 and 100, and but 9 between 1 and 10, and so in all 999, which is not the ninth part of the former.

Definition XVI.

IF the radius AD (*Fig. 113.*) be conceived to move equally about the point A through the periphery of the quadrant DB, while in the mean time the side of the square DC remaining always parallel to it self, descends also with an equal motion thro' DA, so that in the same moment the radius AD and the aforesaid side DC shall fall upon the base AB; or (if any one should think that this way the proportion of a right line to a circular one is supposed by a sort of *Petitio Principii* or begging the question) the right line DA as well as the quadrant DB being divided into as many equal parts as you please (*e.g.* here both of them into 8) and drawing thro' these from the center A so many Radii and thro' them parallel lines; the points of intersection being orderly connected together will exhibit a curve line, whose invention is attributed to *Dionysius* and *Nicomedes* in the fourth Book of *Pappus Alexandrinus*, and which from its use is called a *Quadratrix*, it having among the rest this property, that from AB it cuts off a part AE, which is a third proportional to the quadrant DB and its radius DA; which hereafter we will demonstrate. In the mean while from this description of it, you have these

CONSECTARYS.

I. IF thro' any point H assumed in the *Quadratrix* you draw the radius AH, and from the same point the perpendiculars Hb and He, the whole arch DB will always be to the part IB cut off, as the whole line DA to the part bA cut off, or He equal to it.

II. Consequently therefore any given arch or angle of the quadrant *e.g.* IB or IAB may by help of the quadratrix be divided into three equal parts or as many as you please, or in what proportion soever you will; while having drawn the radius AI, the perpendicular Ha let fall from the point of the quadratrix H, may be divided into three or as many equal parts as you please, or in any proportion whatsoever, and thro' these sections radius's drawn to divide the arch.

B O O K II.

SECTION II.

CHAP. I.

Of the chief Properties of the Conick Sections.

Proposition I.

(*α*) I. Property of the Parab. Apoll. Prop. 11. Lib. 1.

IN the Parabola (GKEH Fig 114) the (*α*) square of the semi-ordinate (IK) is equal to the rectangle IL made by the Latus Rectum EL and the abscissa EI.

Demonstration.

MAke the sides of the cone that is supposed to be cut, $AB = a$, $BC = b$, and moreover $EB = oa$, and $EI = eb$, and $AC = c$; therefore NI will be $= ec$, by reason of the similitude of the $\triangle \triangle BCA$ and EIN ; and EP or IO $= oc$, by reason of the similitude of the $\triangle \triangle ABC$ and EBP . Therefore $\square NIO = oecc = \square IK$ by the Schol. of Prop. 34 (*n. 3*) and Prop 17. Lib. 1. Now if a line be sought which with the abscissa EI shall make the $\square IL = \square IK$ you will have

have it by dividing the said square by the Abscissa EI. viz.
 $\frac{occ}{eb}$ i. e. $\frac{occ}{b} = EL$. And this is called the *Latus Rectum*,

viz. in relation to the Abscissa EI with which it makes that rectangle, which, it's evident, is $= \square IK$, and from this equality the section has the name of Parabola, in *Apollo-nius*.

CONSECTARYS.

I. **T**His *Latus Rectum*, expressed by the quantity $\frac{occ}{b}$,

may be found out after a shorter way, if you make as b to c (the side of the cone parallel to the section BC at the Diame-ter of the base AC) so oc (the side EP called by some the *Latus Primarium*) to a fourth.

II. But if any one, with *Apollonius*, had rather express this by meer *data* in the cone it self as cut (because oc or that *Latus Primarium* EP is not a line belonging to the cone it self) he may easily perceive, if the quantity of the *Latus Rectum* found above, be multiplied by the other side of the cone a , there will be produc'd the equivalent $\frac{oa}{ab}$ which instead of the

proportion above will furnish us with this other,

as ab — to cc — so oa } to a fourth ;
 \square of AB into BC — \square AC — EB }

which is the very proportion of *Apollonius* in *Prop. 9. Lib. 1.* and confirms our former.

SCHOLIUM I.

Hence you have an easie and plain way of describing a Parabola, having the top of the ax and the *Latus Rectum* given, viz. by drawing several semiordinates whose extreme points connected together will exhibit the curvity of the Parabola. But you may find as many semiordinates as you please, if having cut off as many parts of the Ax as you please, you find as many mean proportionals between the
Latus

Latus Rectum and each of those parts or Abscissa's. See n. 2. and 3. Fig. 47. *Introduct. to Specious Analysis.*

S C H O L I U M II.

Hence also we have a new genesis of the parabola in *Plano* from the speculations of *De Witte*, viz. if the rectilinear angle HBG (Fig. 115.) conceived to be moveable about the fixed point B be conceived so to move out of its first situation with its other leg BH along the immoveable rule EF, that it may at the same time move also the ruler HG, from its first situation DK, all along parallel to it self, and with the other leg BG let it all along cut the said ruler HG, and with this point of its intersection continually moving from B towards G it will describe a curve. That this curve will be the parabola of the antients is hence manifest, because it will have this same first property of the parabola. For, 1. if the angle HBG (n. 1.) be supposed to be a right one, and BD or HI $\equiv a$, BI or KG $\equiv b$ (viz. in that station of the angle and rule HG by which they denote the point G in the intersection) you'll have by reason of the right angle at B, BI, i. e. b a mean proportional Between HI i. e. a , and IG or BK, and so this as an abscissa $\equiv \frac{bb}{a}$. Wherefore if BK i. e. bb

be multiplied by BD $\equiv a$, the rectangle DBK will be $\equiv bb$ $\equiv \square$ KG; which is the first property of the parabola: So that it follows, since the same inference may be made of any other point in this curve, that this curve will be the parabola, BD or HI its *Latus Rectum*, KG a semiordinate, and BK its axis, &c. 2. If the angle HBG be an oblique one (num. 2.) it may be easily shewn from what we have supposed that the \triangle DBH and BKG will be equiangular: Therefore as BD (i. e. a) to DH sc. BI (i. e. b) so KG sc. BI (i. e. b) to BK (i. e. bb). Therefore again the \square DBK $\equiv \frac{bb^2}{a}$

KG. Q E D.

Consect. 3. It is also evident in this second case, that BK drawn parallel to the ax, but not thro' the middle of the parabola

parabola, will be a diameter which will have for its vertex B, its *Latus Rectum* BD, and semiordinate GK, &c.

Consect. 4. Therefore you may find the *Latus Rectum* in a given parabola geometrically, if you draw any semiordinate whatsoever IK (Fig. 116.) and make the abscissa EF equal to it, and from F draw a parallel to the semiordinate IK, and from E draw the right line EK thro' K cutting off FH the *Latus Rectum* sought; since as EI to IK so is EF (i. e. IK) to FH by *Prop 34. lib. 1.* wherefore having the abscissa and semiordinate given arithmetically, the *Latus Rectum* will be a third proportional.

Consect. 5. Since therefore the *Latus Rectum* found above is $\frac{occ}{b}$, if you conceive it to be applied to the parabola in LM,

so that N shall be that point which is called the *Focus*, LN will be $\frac{occ}{2b}$ and its square $\frac{occ^2}{4bb}$ and this divided by the *Latus Rectum* $\frac{occ}{b}$ will give $\frac{occ}{4b}$ for the abscissa EN: So that the distance of the *Focus* from the *Vertex* will be $\frac{1}{4}$ of the *Latus Rectum*.

Consect. 6. Since therefore EN is $\frac{occ}{4b}$, if for EF you put ib , NF will be $\frac{ib^2 - occ}{4b}$, whose square will be found to be

$$\frac{i^2b^2 - oibc + o^2c^4}{2 \quad 16b^2}$$

by *Prop. 1.* the square of NG will be $\frac{i^2b^2}{2} + \frac{oibc}{2} + \frac{o^2c^4}{16b^2}$

whose root (as the extraction of it and, without that, the analogy of the square NF with the square NG manifestly shews) will be $ib + \frac{occ}{4b}$; so that a right line drawn from the *Focus* to

the end of the ordinate, will always be equal to the abscissa EF + EN

† EN *i. e.* (if EO be made equal to EN) to the compounded line FO.

S C H O L I U M III.

Hence you have an easier way of describing the parabola in *Plano* from the given *Focus* and *Vertex*, *viz.* (Fig. 117.) the axis being prolonged thro' the vertex E to O, so that EO shall = EN, if a ruler HI be so moved by the hand G, according to PQ, from OF to HI, that putting in a style or pin, it shall always keep the part of the Thred NGI (which must be of the same length with the rule HI) as fast as if it were glued to it (which perhaps might also be done with the Compasses by an artifice which we will hereafter also accommodate to the hyperbola) and at the same time it will describe in *Plano* the part of the line EGR. That this will be a parabola is evident from the foregoing Consect. because as the whole thred is always = to the ruler IH; so the part GN is always necessarily equal to the part GH, *i. e.* to the line FO. Moreover from the same sixth Consect. and Fig. 116. may be drawn another easie way of describing the parabola in *Plano* from the *Focus* and *Vertex* given thro' innumerable points G to be found after the same way: *viz.* If from any assumed point in the ax F you draw to the ax a perpendicular, and at the interval FO from the *Focus* N you make an intersection in G. Which innumerable points G will be determined with the same facility, having given only, or assumed the axis and *Latus Rectum*, by virtue of the present Proposition. For if, having assumed at pleasure the point F in the axis, you find a mean proportional between the *Latus Rectum* and the abscissa EF, a semiordinate FG made equal to it, will denote or mark the point G in the parabola sought.

Proposition II.

IN the hyperbola (GKEH Fig 118) (a) the square of the semiordinate (IK) is equal to the rectangle (IL) made of the Latus Rectum (EL) and the abscissa (EI) together with another rectangle LS of the said abscissa (EI or LR) and RS a fourth proportional to DE the Latus Transversum, (EL) the Latus Rectum, and EI the Abscissa.

(a) I. Property of the Hyperb. Apoll. Prop. 12. Lib. 1.

Demonstration.

Suppose the side of the cone AB here also $\equiv a$, and BM parallel to the section $\equiv b$, and the intercepted line AM $\equiv c$, and EI $\equiv eb$; all according to the analogy we have observed in the parabola; and NI will be as there $\equiv ec$. Making moreover MC $\equiv d$ and the Latus Transversum DE $\equiv ob$, so that DI shall be $\equiv ob + eb$; then will (by reason of the similitude of the $\triangle \triangle$ BMC, DEP, and DIO) EP be $\equiv od$, and IO $\equiv od + ed$, and so QO $\equiv ed$. Therefore \square NIO will be $\equiv oecd + eecd \equiv \square$ IK. But this square divided by the Abscissa EI $\equiv eb$ gives $\frac{oecd + eecd}{eb}$ or $\frac{ecd + ecd}{b}$ for the

line IS which with the abscissa would make the rectangle ES \equiv to the said square IK. Now therefore, if here also we call a Line the Latus Rectum found after the same way as in the parabola, viz by making

as b — to c — so od to a fourth $\frac{odc}{b}$

(as a line parallel to the section — to the intercepted diam. so the Latus Primarium, but that the other part $\frac{ecd}{b}$ will be a

fourth proportional to bc and ed or to eb , ec and ed , or (to speak with Apollonius as we have done in the Prop.) to ob , ecd and eb (for in these three cases you have the same fourth $\frac{ecd}{b}$)

Wherefore now it is evident that the square of the se-

O

miordinate

miordinate $oecd + eecd$ is equal to the rectangle IL (made by the *Latus Rectum* $\frac{ocd}{b}$ into the abscissa $eb = oecd$) together

with \square LS of this fourth proportional $\frac{ecd}{b}$ into the same ab-

scissa Eb, which is $= eecd$. Which was to be found and demonstrated.

CONSECTARYS.

I. **H**ence you have in the first place the reason why *Apollonius* called this Section an Hyperbola; viz. because the square of the ordinate IK exceeds or is greater than the rectangle of the *Latus Rectum* and the Abscissa.

II. Since therefore the *Latus Rectum* here also as well as in the parabola is found by making as b to c so od to $\frac{odc}{b}$ (i.e. as

the parallel to the section BM is to the intercepted Diam. AM so is the *Latus Primarium* EP to a fourth EL.) If any one had rather express this *Latus Rectum* after *Apollonius's* way, he will easily perceive, this quantity being found and multiplied both Numerator and Denominator by b the parallel to the section, there will come out the equivalent quantity $\frac{obcd}{bb}$

which gives us instead of the former proportion this other,

as bb — to cd — so ob —

\square BM — \square AMC — *Latus Transversum* } to a fourth;
which is that of *Apollonius* in Prop. 12. Lib. 1. and consequently herein confirms our former.

III. You may also have this *Latus Rectum* geometrically, by finding a third proportional (as we have done in the parabola *Consect.* 4. Prop. 1.) to the abscissa EI (*Fig.* 119.) and the semiordinate IK ($= EF$;) and then find a fourth proportional EL to DI (the sum of the *Latus Transversum* and abscissa) and FH already found, or IS equal to it, and DE (the *Latus Transversum*) and that will be the *Latus Rectum* sought.

S H C O L I U M.

From this third Confectary, we may reciprocally from the *Latus Rectum* and transverse given, find out and apply as many semiordinates to the ax as you please, and so describe the hyperbola thro' their (ends or) infinite points: viz. if assuming any part of the abscissa EI, you make as DE to EL so DI to IS; and then find a mean proportional IK between IS and the abscissa EI, and that will be the semiordinate sought: And both this praxis and the Confect. may be abundantly proved by setting it down in, and making use of, the literal Calculus.

Proposition III.

IN the Ellipsis (KDEK, Fig. 120.) the (a) square of the semiordinate (IK) is equal to the rectangle (IL) of the *Latus Rectum* (EL) and the abscissa (EI) (less or) taking first out another rectangle (LS) of the same abscissa (EI or LR) and RS a fourth proportional to (DE) the *Latus Transversum* (EL) the *Latus Rectum* and (EI) the abscissa.

(a) I. Propert. of the Ellipse of Apoll. Prop. 13. lib. 1.

Demonstration.

Suppose the side of the cone to be AB here also $\equiv a$ and BM parallel to the section $\equiv b$ and the intercepted AM $\equiv c$, and EI $\equiv eb$; and NI will be again $\equiv ec$, all as in the hyperbola. And making also here as in the hyperbola MC $\equiv d$, and the *Latus Transversum* DE $\equiv ob$, so that DI will be $ob - eb$; then will (by reason of the similitude of the $\triangle \triangle$ BMC, DEP and DIO) EP be $\equiv od$, and IO $\equiv od - ed$. Therefore \square of NIO will be $\equiv oecd - eecd \equiv \square IK$. But this square divided by the abscissa EI $\equiv eb$ gives $\frac{oecd - eecd}{eb}$ or $\frac{ecd - ecd}{b}$ for that line IS which with

the abscissa would make the rectangle ES \equiv to the said square IK. Now therefore if we call the *Latus Rectum* a right line found after the same way as in the parabola, by making according to Conf. I. Prop. I.

as b to c — so od — to a fourth $\frac{ocd}{b}$ i. e. as the line parallel to the section — to the intercepted diameter — is the *Latus Primarium*, &c. It is manifest that the *Latus Rectum* is one part of the line just now found; and the other part $\frac{ecd}{b}$ is a fourth proportional to b , c and ed , or (to speak with *Apollonius* as we have done in the Prop.) to ob , $\frac{ocd}{b}$ and eb (for there will come out the same quantity $\frac{ecd}{b}$;) wherefore now it is evident that the \square of the semiordinate IK is equal to the \square IL (of the *Latus Rectum* $\frac{ocd}{b}$ and the abscissa $eb \equiv oecd$) having first taken out thence the \square LS , or $eced$ out of that fourth proportional $\frac{ecd}{b}$ by the same abscissa eb ; which was to be found and demonstrated.

CONSECTARYS.

I. **H**ence you have first of all the reason of the name of the *Ellipse*, which *Apollonius* gave to this section; viz. because the square of the semiordinate IK is defective of, or less than the rectangle of the *Latus Rectum* and the abscissa.

II. Since therefore the *Latus Rectum* here also as well as in the parabola and hyperbola, is found by making as b to c so od to $\frac{ocd}{b}$ (i. e. as BM parallel to the section is to the intercepted diam. AM so the *Latus Primarium* EP to a fourth EL) now if any one had rather express this *Latus Rectum* after *Apollonius's* way, he will easily see that the quantity above found being multiplied both Numerator and Denominator by b , that there will come out an equivalent one $\frac{obcd}{bb}$, which instead of the former proportion will give this other,

as bb — to cd — so ob
 BM — \square AMC — *Latus Transvers.* } to a fourth;

which is the same with that we have also found in the hyperbola, and which also *Apollonius* has *Prop. 13. Lib. 1.*

III. This *Latus Rectum* may also be had geometrically, if you find, 1. in the hyperbola a third proportional FH to the abscissa EI (*Fig. 121.*) and semiordinate IK ($\square EF$.) 2. But EL a fourth proportional to DI (the difference of the *Latus Transversum* and the abscissa) and the found FH , or IS equal to it, and the *Latus Transversum* DE , is the *Latus Rectum* sought.

S C H O L I U M.

FROM this third Consect. we may reciprocally, having the *Latus Rectum* and *Transversum* given, apply as many semiordinates to the ax as you please, and so draw the ellipsis thro' as many points given as you please, viz. if taking any abscissa EI , you make as DE to EL so DI to a fourth IS ; then between this IS and the abscissa EI find a mean proportional IK , and that will be the semiordinate sought: And this *Praxis* is also and the third Consect. may be abundantly proved by making use of a literal *Calculus*. For e. g. here a fourth proportional to ob , $\frac{acd}{b}$ and $ob - eb$ will be $\frac{ecd - ecd}{b}$; and a mean proportional between this fourth and eb will be $\sqrt{acd - eecd}$, &c.

Proposition IV.

IN a Parabola (α) the squares of the ordinates are to one another as the abscissas.

(α) 2. Property of the Parab. 20. Prop. Apoll. Lib. 1. Con.)

Demon.

Demonstration.

For if EF (Fig. 122.) be called *ib*, as above EI was called *eb*, since the *Latus Rectum* is $\frac{occ}{b}$; the square of FG will

be $\equiv oicc$. Therefore

$\square IK$ will be to $\square FG$ as $\left. \begin{array}{l} e \text{ to } i \\ eb \text{ to } ib \end{array} \right\}$ or
 $oicc \text{ --- } oicc$ Q. E. D.

CONSECTARY.

Hence having drawn LO parallel to the ax or diameter EF, if it be cut by the transverse line EG in M and by the curve of the parabola in K; then will OL, ML, and KL be continual proportionals. For EF is to EN as FG to NM or IK, by reason of the similitude of the $\triangle EFG$ and $\triangle ENM$. But the squares FG and IK are in duplicate proportion of EF to EN by *Prop. 35. Lib. 1.* and are also in the same proportion as the abscissas EF and EI by the pref. Therefore EF to EI is also in duplicate proportion of EF to EN *i. e.*

$\left\{ \begin{array}{l} EF \\ OL \end{array} \right\}$ is to $\left\{ \begin{array}{l} EN \\ ML \end{array} \right\}$ as $\frac{EN}{ML}$ to $\frac{EI}{KL}$ } Q. E. D.

Proposition V.

(α) Property of the Hyperbola and Ellipsis. *Apol. 21. Lib. 1.*

IN the hyperbola and Ellipsis (α) the squares of the Ordinates are as the rectangles contained under the lines which are intercepted between them, and the Vertex's of the Latus Transversum's.

Demonstration.

For, if EF (Fig. 118. and 120.) be called *ib*, as EI was above called *eb*, then will according to *Prop. 2.* and the 3^d. deduction.

$GF \equiv oicd + eicd$ in the Hyperb.
 $oicd - eicd$ in the Ellipsis.
 and the $\square DFE \equiv oibb + iibb$ in the Hyperb.
 $oibb - iibb$ in the Ellipsis.

There-

Therefore the \square KI is to the square GF as $oe\overset{+}{cd} + ee\overset{+}{cd}$ to $oicd + iicd$ i. e. as $oe + ee$ to $oi + ii$.
 and \square DIE is to the \square DFE, as $oe\overset{+}{bb} + ee\overset{+}{bb}$ to $oibb + iibb$
 i. e. in like manner as
 $oe + ee$ to $oi + ii$. Q. E. D.

CONSECTARY I.

IN the Ellipsis this may be more commodiously expressed apart thus; the squares of the ordinates (KI and GF) are as the rectangles contained under the segments of the Diameter (*viz.* DIE and DFE) in which sense this property is also common to the circle, as in which the squares of the ordinates are always equal to the rectangles of the segments.

CONSECTARY II.

Therefore, if the *Latus Rectum* be conceived to be applied in the hyperbola, so that N shall be the *Focus*; (see Fig. 123.) then will $LN = \frac{ocd}{2b}$, and its square be $\frac{oocdd}{4bb}$. But

as the \square KI to the square LN, so is the \square DIE to the \square DNE i. e. $oe\overset{+}{cd} + ee\overset{+}{cd}$ to $\frac{oocdd}{4bb}$ so is $oe\overset{+}{bb} + ee\overset{+}{bb}$ to $\frac{oocd}{4}$. But

now the \square of the whole DE and the part added EN into the part added EN, i. e. \square DNE ($= \frac{oocd}{4}$ together with

the square of half CE ($= \frac{oobb}{4}$) is $= \square$ compounded of half

and the part added CN $= \frac{oocd + oobb}{4}$ by Prop. 9. lib. 1.

Wherefore CN the distance of the *Focus* from the centre is $= \sqrt{\frac{oocd + oobb}{4}}$. But $\frac{oocd}{4}$ is the fourth part of the \square of

the *Latus Transversum* ob and the *Latus Rectum* $\frac{ocd}{b}$ (or the

fourth

fourth part of the figure, as *Apollonius* calls it) and \overline{oobb} is the

\square of \overline{ob} i. e. of half the *Latus Transversum*. Wherefore we

have found the following Rule of determining the *Focus* in an hyperbola: If a fourth part of the figure (or the rectangle of the *Latus Rectum* into the *Transversum*) be added to the square of half the *Latus Transversum*, and from the sum you extract the square root; that will be the distance of the *Focus* from the center *CN*: And hence subtracting half the *Latus Transversum* *CE*, you will have distance of the *Focus* from the Vertex *EN*.

CONSECTARY III.

IN like manner in the *Ellipsis* having drawn the ordinate *LM* (*Fig. 124.*) that the *Focus* may be in *N*, the \square *LN* would be \overline{oocdd} as above, and by a like inference \square *DNE* =

\overline{oocd} . But now \square *DNE* together with the square of the dis-

ference *CN* is equal to the \square of half *CE* by *Propos. 8. lib. 1.* and consequently the \square *CN* is = \square *CE* — \square *DNE*, that is, \overline{oobb} — \overline{oocd} . Wherefore *CN* the distance of the *Focus*

from the centre is = $\sqrt{\overline{oobb} - \overline{oocd}}$. Wherefore we have

found the following Rule to determine the *Focus* in the *Ellipse*. If the fourth part of the figure (or the rectangle of the *Latus Rectum* into the *Latus Transversum*) be subtracted from the square of half the *Latus Transversum*, and from the remainder you subtract the square root; that will be the distance of the *Focus* from the Centre *CN*: And taking hence half the *Latus Transversum* *CE*, you'll have the distance of the *Focus* from the Vertex *EN*.

SCHOLIUM I.

BOTH the Rules are easie in the practice, for since $\frac{oobb}{4}$ is nothing but the square of CE, and $\frac{oocd}{4}$ nothing but the rectangle of $\frac{1}{4}$ DE into LM; if between LM and $\frac{1}{4}$ DE or MO (Fig. 125.) you find a mean proportional MN, (and so whose \square is equal to that \square) and in the hyperbola join to it at right angles MC = CE, the hypothenusa CN will be the distance sought of the Focus from the centre: And the same may be had in the Ellipsis, if (n. 2.) having described a semi-circle upon CM = CE you draw or apply the mean found MN, and draw CN.

SCHOLIUM II.

HENCE also we have (a) a new genesis of the Ellipse in Plano about the diameters given, from the speculations of Monsieur de Witt; viz. If about the rectilinear angle DCB (Fig. 126. n. 1. and 2.) consider'd as immovable, the rule NLK (which all of it will equal the greater semidiameter CB, and with the prominent part LK the lesser CD) be so moved that N going from C to D, and L from B to C may perpetually glide along the sides of the angle, the extreme point in the K in the mean while describing the curve BKE (and in a like application the other quadrants) and that this curve thus described will be the ellipsis of the ancients is hence manifest, because it has the second property of the ellipse just now described. For, 1. if the angle DCB or NCB be supposed to be a right one (as in Fig. 126. num. 1.) and the rule KN in the same station, it marked out the point K, and having apply'd the semiordinate KI, and drawn the perpendicular LM, from the square KL and the square CE (as being equal) subtract mentally the equal squares LM and CI, and there will remain by virtue of the Pythagorick Theor. on the one hand $\square KM$ and on the other by

(a) D^e Witt
Elem. Curv.
Lib. 1. Cap. 3.
Prop. 13.

P

Prop.

Prop. 8. lib. 1. \square DIE equal among themselves. But now the square of KI is to the square of KM (*i. e.* to the \square DIE) as the square of KN to the square of KL (*i. e.* as the square of CB to the square of CE) by reason of the similitude of the $\triangle \triangle$ KLM and KNI; and since the same may be demonstrated after the same manner of any other semiordinate Ki *viz.* that its \square Ki is to the \square DiE as the square CB to the square CE. It also follows, that the \square KI is to the \square DIE as \square Ki to the \square DiE, and alternatively, the square KI will be to the square Ki as the \square DIE to the \square DiE; which is the second property of the ellipse. 2. If the angle NCE be not a right one (as in *Fig. 126. n. 2.* and the like cases) having drawn NO and KP parallel to the rule n/B in the first station, [in which station the angle NCE, to which the flexible ruler is to be made, is determined, *viz.* by letting fall the perpendicular B/ from the extremity of one diameter upon the other, and moreover by adding or subtracting the difference of the semi-diameters ln] having also drawn the Ordinate KIM, and PI parallel to CN; which being done the $\triangle \triangle$ CBI and IKF, and also CB n and IKP will be similar. Wherefore having joined NP, from the parallelism of the lines IP and NC and the similitude of the aforesaid $\triangle \triangle$, as also of NCO and nCl , it will be easie to conclude that NCIP is a parallelogram. Wherefore since KN is \equiv CE and \square KN \equiv \square CE, having subtracted the squares of the equal lines NP and Cl, there will remain on the one hand \square KP on the other the \square DIE equal among themselves as above. Therefore the square of KI will be to the square of KP (*i. e.* to the \square DIE) as the square of BC to the square of B n (*i. e.* to the square of CE) as in the former case: And since here also the same may be demonstrated after the same manner of any other semiordinate Ki ; we may infer as above, that the \square KI and Ki are to one another as the rectangles DIE and DiE, &c.

But after what way the same ellipses may be described by these right lined angles without any of these rulers thro' infinite points given, will be manifest from the same figures to any attentive Person. For having once determined the angle NCE or nCD (*num. 2. e. g.*) if NL or nI be applied where you please by help of a pair of compasses, and continued to

K, so that LK or lk shall be equal to lB , you will have every where the point K, &c.

CONSECTARY IV.

Since in the hyperbola (Fig. 123.) the $\square CN - \square CE = \square DNE$, and in the ellipsis (Fig. 124.) $\square CE - \square CN = \square DNE$, by vertue of Prop. 9 and 8. lib. 1 if for CN you put on both sides for brevity's sake m , then will the $\square DNE$ in the hyperbola be rightly exprest in these terms $\frac{mmb}{4}$, and in the ellipsis in these $\frac{oobb}{4} - mm$.

Proposition VI.

In the parabola (a) the Latus Rectum is to the sum of two semiordinates (e. g. $IK + FG$ i. e. HO in Fig. 122.) as their difference (OG) to the difference of the abscissa's (IF or KO.)

(a) 3. Property of the Parab.

Demonstration.

For if the greater abscissa EF be made $= ib$, and the less $El = eb$, the semiordinates answering to them FG and IK will be \sqrt{oicc} and \sqrt{oecc} as is deduc'd from Prop. 1. Wherefore if you set in the same series

$$\begin{array}{ccccccc} \overset{1}{\text{The Latus R.}} & \overset{2}{\text{sum of the semiord.}} & \overset{3}{\text{their diff.}} & & & & \\ \frac{oicc}{b} & \text{---} \sqrt{oicc} + \sqrt{oecc} & \text{---} \sqrt{oicc} - \sqrt{oecc} & & & & \\ & \overset{4}{\text{--- diff. of the absciss.}} & & & & & \\ & \text{--- } ib - eb & & & & & \end{array}$$

and multiply the extremes and means, you'll have on both sides the same product $oicc - oecc$, which will prove by vertue of Prop. 19. lib. 1. the proportionality of the said quantities. Q. E. D.

S C H O L I U M.

THis is that property of the parabola, whereon the *Clavis Geometrica Catholica* of Mr. Thomas Baker is founded, which as unknown to the ancients, nor yet taken notice of by Des Cartes, he thinks was the reason why that incomparable Wit could not hit upon those universal rules for solving all Equations howsoever affected. Concerning which we shall speak further in its place. We will only further here note, that Baker was not the first Inventor of this property, but had it, as he himself ingeniously confesses, out of a Manuscript communicated to him by Tho. Storde of Maperton, Esquire.

Proposition VII.

(a) The 3.
Property of the
Hyperb. and El-
lips. Apollon.
lib. 1. Prop. 21.
pars prior.

IN the hyperbola and ellipsis (a) the *Latus Rectum* is to the *Latus Transversum*, as the square of any semiordinate (e. g. IK in Fig. 118 and 120.) to the rectangle (DIE) contained under the lines intercepted between it and the Vertex's of the *Latus Transversum*.

Demonstration.

For the *Latus Rectum* is on both sides $\frac{ocd}{b}$, the *Latus Transversum* ob, &c. Wherefore if you make in the same series as the *Latus R.* to the *Lat. Transv.* so the $\square IK$ to $\square DIE$ $\frac{ocd}{b} - ob$ — in hyperb. $ocd + cecd - oebb + eebb$ in ellips. $ocd - eecd - oebb - eebb$
The rectangles of the extremes and means will both be $oeekd + oeecbd$, and so will prove the proportionality of the said quantities, by Prop. 19. lib. 1. Q. E. D.

CONSECTARY I.

Hence having given in the ellipsis (see Fig. 124) the *Latus Rectum* and the transverse ax, you may easily obtain the second ax or diameter, if you make as the *Lat. Transv.* to the *Lat. Rect.* so the \square DCE to \square AC

$$\frac{ob}{b} = \frac{ocd}{b} = \frac{oobb}{4} F. = \frac{oocd}{4}$$

CONSECTARY II.

Therefore the \square of the whole AB will be $\square oocd = \square$ of the *Latus Rectum* into the *Lat. Transv.* (which *Apollonius* calls the *Figure*) so that the second Ax (and any second Diameter) will be a mean proportional between the *Latus Rectum* and the *Latus Transversum*. Hence in the hyperbola also the second or conjugate diameter may be called a mean proportional between the *Latus Rectum* and *Transversum*, i. e. \sqrt{oocd} or a line which is equal in power to the *Figure*, as *Apollonius* speaks.

SCHOLIUM I.

Hence may be derived another and more simple way of delineating organically the ellipsis in *Plano* about the given axes AB, DE (Fig 127.) which *Schooten* has given us; viz. by the help of two equal rulers CG and GK moveable about the points G and G : If, viz. the portions CF and HK are equal to half the lesser ax AC, but taken with both the augments (viz. CF + FG + GH) may $\square \frac{1}{2}$ the greater ax CD or CI; and the point K moving along the produced line DE the point H may describe the curve EHAD. That this will be an ellipsis will be evident by vertue of this seventh Prop. from a property that agrees to this curve in all its points H. For having drawn circles about each diameter, and the lines IHN, FO perpendicular to CE; and having made the *Latus Rectum* EL, which is a third proportional to DE and AB by the second Consect. of this Prop. &c. by reason of the similitude of the triangles CFO, CIN, FO will be to FC as IN

IN to IC, and alternatively FO to IN as FC to IC *i. e.* as AC to CE or AB to DE. Therefore also the square of FO (or HN) will be to the square of IN, as the square of AB to the square of DE, by *Prop. 22. lib. 1. i. e.* as EL the *Latus Rectum* to ED the *Latus Transversum*, by *Prop. 35. lib. 1.* But the \square IN is \equiv DNE from the property of the circle. Therefore \square FO (or of the semiordinate HN) is to the \square DNE as EL the *Latus Rectum* to ED the *Latus Transv.* therefore by virtue of the *pref. Prop.* the point H is in the *Ellipsis*, and so any other, &c. Q. E. D.

CONSECTARY III.

NOW if in the ellipsis the \square of AC the second Ax (\equiv *oocd* by *Consect. 1.*) and \square CN the distance of the Fo-

⁴
cus from the centre (\equiv *oobb* — *oocd* by *Consect 3. Prop. 5.* the

⁴
figure whereof you may see *n. 124.*) be joined in one sum; the \square AN will be \equiv *oobb*, and so the line AN \equiv $\frac{ob}{2}$ *i. e.* to

⁴
half the *Latus Transversum*: So that hence having the axes given you may find the *Foci*, if from A at the interval CD you cut the transverse ax in N and N.

CONSECTARY IV.

NOW if, on the contrary, in an hyperbola (*Fig. 123.*) the \square AC or EF \equiv *oocd* be subtracted from the \square CF

⁴
or CN \equiv *oobb* + *oocd* by virtue of *Consect. 2. Prop. 5.* there

⁴
will remain *oobb* and its root $\frac{ob}{2}$, *i. e.* half the *Latus Trans-*

⁴
versum CD: So that here also, the axes being given, you may find the *Focus*'s, if from the vertex E you make EF a perpendicular to the ax \equiv to the second Ax AC, and at the interval CF from the centre C you cut the *Latus Transversum* continued in N and N.

SCHOLIUM II.

BUT now, that the right lines KN and KN drawn from any other point (*e. g.* K) to the *Foci*, when taken together in the ellipsis, but when subtracted the one from the other in the hyperbola, are equal to the *Latus Transversum* DE, we will a little after demonstrate more universally, and also shew an easie and plain *Praxis* of delineating the ellipsis and hyperbola in *Plano*, having the axes and consequently the *Foci* given.

CONSECTARY V.

SINCE we have before demonstrated *Consect.* 2. and 3. *Prop.* 5. that the \square DNE in the hyperbola and also in the ellipsis is $\equiv \frac{4}{\text{ocd}}$; and here in *Consect.* 1. the \square of the second semi-diameter AC is also $\equiv \frac{4}{\text{ocd}}$; it is evident that this \square AC is equal to the \square DNE.

CONSECTARY VI.

IT is hence moreover evident, if the square of half the transverse diameter GE $\equiv \frac{4}{\text{obb}}$ be compared with the square of half the second diameter AC or EF $\equiv \frac{4}{\text{ocd}}$, multiplying both sides by 4 and dividing by *o*; they will be to one another as *obb* to *ocd* i. e. further dividing both sides by *b*, as *ob* to $\frac{\text{ocd}}{b}$ the *Latus Transversum* to the *Latus Rectum*.

CONSECTARY VII.

BUT since also the \square DIE is to the \square IK as the *Latus Transversum* to the *Latus Rectum*, by vertue of the present 7. *Prop.* the square of CE the transverse semidiam. will be to

to the square of AC the second semidiam. (or by the 5th. Consect. of this, to the \square DNE) as the \square DIE to the square of IK.

CONSECTARY VIII.

YOU may also now have the \square IK (which otherwise in the hyperb. is $eecd + eecd$, in the ellipse $eecd - eecd$, by virtue of Prop. 2. and 3.) in other terms, if you make as \square CE to the \square DNE so the \square DIE to a fourth; i. e.

as $\frac{oobb}{4}$ to $\frac{mm}{4}$ — $\frac{oobb}{4}$ } by virtue of Consect. 4. Prop.

4 4 5.

(so $eobb + eebb$ in the hyperb.

as $\frac{oobb}{4}$ to $\frac{oobb}{4}$ — mm so $eobb - eebb$ in the ellipsis.

4 4

For hence by the Golden Rule the square IK may be infer'd as a fourth proportional.

In the hyperbola $\frac{4emm}{0} + \frac{4eemm}{00} - eobb - eebb$;

In the ellipsis $eobb - eebb - \frac{4emm}{0} + \frac{4eemm}{00}$:

The use of which quantities will presently appear.

Proposition VIII.

(a) Apollon. **T**HE { Aggregate in the ellipse } of the right
Lib. 3. Prop. 51. { Difference in the hyperb. } lines (a) KN and Kn (Fig. 128.) drawn
and 52. from the same point K to both the Focus's is equal
to the transverse ax DE.

An Ocular Demonstration.

WHich consists wholly in this to find the lines KN and Kn by help of the right-angled triangles IKN and IKn (sc. the hypotenuses having the sides given) and afterwards see if the sum of both in the ellipse, and difference in the hyperbola be $= ob$, i. e. to the transverse ax DE.

I. In the Ellipsis.

Putting for CN (which above Prop. 5. Conf. 3. was found to be $\sqrt{oobb - oocd}$) I say putting for it m , you'll have

$$\begin{aligned} IN &= CI + CN = \frac{1}{2}ob - eb + m \\ In &= Cn - Ci = m - \frac{1}{2}ob + eb \\ \text{Therefore } \square IN &= \frac{1}{4}oobb - oebb + eebb + obm - 2ebm + mm \\ \square In &= \frac{1}{4}oobb - oebb + eebb - obm + 2ebm + mm \\ \text{Add to each } \square IK &\text{ which was found in Prop. 7. Confect. 8. in} \\ &\text{the ellipsis } = oebb - eebb - \frac{4emm}{0} + \frac{4emm}{00} \text{ and you'll have} \end{aligned}$$

$$\square KN = \frac{1}{4}oobb + obm - 2ebm + mm - \frac{4emm}{0} + \frac{4emm}{00}$$

and by extracting the roots (which is easie) you'll have

$$KN = \frac{1}{2}ob + m - \frac{2em}{0} \text{ and}$$

$$Kn = \frac{1}{2}ob - m + \frac{2em}{0}$$

Sum ob. Q. E. D.

II. In the Hyperbola.

Putting again m for CN (which above Conf. 2. Prop. 5. was found to be $\sqrt{oocd + oobb}$) and you'll have

$$\begin{aligned} IN &= CI + CN = \frac{1}{2}ob + eb + m \\ In &= CI - Cn = \frac{1}{2}ob + eb - m. \text{ Therefore} \\ \square IN &= \frac{1}{4}oobb + oebb + eebb + obm + 2ebm + mm \text{ and} \\ \square In &= \frac{1}{4}oobb + oebb + eebb - obm - 2ebm + mm \\ \text{Add to both the } \square IK &\text{ which was found in Prop. 7. Confect. 8. in the hyperbola } \frac{4emm}{0} + \frac{4emm}{00} - oebb - eebb \text{ and} \end{aligned}$$

you'll have

$$\square KN = \frac{1}{4}oobb + obm + 2ebm + mm + \frac{4emm}{0} + \frac{4emm}{00}$$

Q

□ K_n

$$\square Kn = \frac{1}{2}obb - obm - \frac{2ebm}{0} + mm + \frac{4emm}{0} + \frac{4eemm}{00}$$

and extracting the roots out of these (which is easie) you'll have $KN = \frac{1}{2}ob + m + \frac{2em}{0}$

$$Kn = \frac{1}{2}ob - m - \frac{2em}{0}$$

(which is a false or impossible root, for it would be $CE - CN$ and moreover — another quantity.

Or $Kn = m + \frac{2em}{0} - \frac{1}{2}ob$; which is a true and possible root.

The difference therefore of the true roots is $= ob$. Q. E. D.

SCHOLIUM I.

WE first of all tried to make a literal Demonstration by using the quantity of the square IK as you have it expressed *Prop.* 2. and 3. and the quantity IN as it was compounded of $CI = ob + eb + CN = \sqrt{oodd + oobb}$, &c. but

4

we found it very tedious in making only the squares of IN and In . Then for the surd quantity CN we substituted another, viz. m , and we produced the squares of IN and In as above, but we added the square of IK in its first value; and thus we obtain'd the squares KN and Kn , but in such terms, that the exact roots could not be extracted, but must be exhibited as surd quantities, and consequently we must make use of the rules belonging to them to find their sum or difference, which we laid down *Conf.* 3. *Prop.* 7. and *Consect.* *Prop.* 10. *Lib.* 1. which tho' it would succeed, yet wou'd be full of trouble and tediousness. Therefore at length when we came to use those other terms which express the square IK , the business succeeded as easie as we could wish, and that in a plain and easie way and no less pleasant, which I doubt not but will also be the opinion of the Reader, who shall compare this with other demonstrations of the same thing, which only lead indirectly to this truth, or with them which *de Witte* has given us in *Elem. Curvar. lin. p. m.* 293. and 302. and which he thinks easie

easy and short enough in respect of others both of the ancients and moderns, and which we have reduced into this yet more distinct form, and accommodated to our schemes.

Preparation for the Hyperbola.

Make as $\left\{ \begin{array}{l} \text{CD to CN} \\ \text{EE — CN} \end{array} \right\}$ so CI to CM

so that the \square of $\left\{ \begin{array}{l} \text{DCM} \\ \text{MCE} \end{array} \right\}$ will be $\equiv \square \left\{ \begin{array}{l} \text{NCI} \\ \text{nCI} \end{array} \right\}$.

Because therefore it will be by *Consect. 7. Prop. 7.*

as \square CD to \square DNE, so the \square DIE to the \square IK.

And also by composition,

as \square CD to $\left\{ \begin{array}{l} \square \text{ CD} \dagger \square \text{ DNE} \\ \text{i. e. } \square \text{ CN per 9. lib 1.} \end{array} \right\}$ so DIE to DIE $\dagger \square$ IK.

Therefore by a Syllepsis,

as \square CD to the \square CN so $\left\{ \begin{array}{l} \square \text{ CD} \dagger \text{DIE} \\ \text{i. e. } \square \text{ CI} \end{array} \right\}$ to \square CN \dagger DIE $\dagger \square$ IK.

But also by the Hypothesis.

as the \square CD to the \square CN so \square CI to \square CM. Therefore \square CM is $\equiv \square$ CN \dagger DIE $\dagger \square$ IK.

Demonstration.

Since therefore it is certain that the difference between DM and EM is the transverse ax DE; if it be demonstrated that DM is \equiv KN and EM \equiv K n , the business will be done, because the difference between KN and K n is also the transverse ax DE.

Resolve the \square KN.

It is certain that $\text{NI}q \dagger \text{IK}q \equiv \text{KN}q$.

Substitute for $\text{NI}q$, by the 7. Lib. 1. $\text{CI}q \dagger \text{CN}q \dagger 2\text{NCI}$.

Preparation for the Ellipsis.

Make as CD to CN so CI to CM.

So that the \square DCM is $\equiv \square$ NCI.

Because therefore by *Consect. 7. Prop. 7.*

as \square CD to \square DNE so \square DIE to the \square IK;

Q 2

Then

Then also by dividing,

as \square CD to $\left\{ \begin{array}{l} \square \text{CD} \text{ --- } \text{DNE} \\ \text{i. e. } \square \text{CN, by 8. l. 1.} \end{array} \right\}$ so DIE to DIE — \square IK.

Therefore by a Dialepsis,

as \square CD to $\left\{ \begin{array}{l} \square \text{CD} \text{ --- } \square \text{DIE} \\ \text{i. e. } \square \text{Cl } \square \text{ by 8. cir.} \end{array} \right\}$ to \square CN — DIE \dagger \square IK.

But also by the Hypothesis,

as \square CD to \square CN, so \square Cl to \square CM :

Therefore \square CM is \equiv \square CN — DIE \dagger \square IK.

Demonstration.

Since therefore it is certain that the sum of DM and EM is the transverse ax DE ; if it be demonstrated that DM is \equiv KN and EM \equiv Kn, the business will be done, because the sum of KN and Kn is also equal to the transverse ax DE.

Resolve the \square KN.

It is certain that $\text{Nl}q \dagger \text{IK}q \equiv \text{KN}q$.

Substitute for $\text{Nl}q$, by the 7. lib. 1. $\text{Cl}q \dagger \text{CN}q \dagger 2\text{NCI}$.

Then will $\text{Cl}q \dagger \text{CN}q \dagger 2\text{NCI} \dagger \text{IK}q \equiv \text{KN}q$.

Substitute for $\text{C}q$, by the 9. lib. 1. $\text{CD}q \dagger \text{DIE}$; then will

$\text{CD}q \dagger \text{DIE} \dagger \text{CN}q \dagger 2\text{NCI} \dagger \text{IK}q \equiv \text{KN}q$.

Resolve also \square DM.

It is certain that $\text{CM}q \left\{ \begin{array}{l} 2\text{DCM} \\ 2\text{NCI} \end{array} \right\} \equiv \text{DM}$, by the 7 lib. 1.

$\dagger \text{CD}q \dagger$

Substitute for $\text{CM}q$ its value by the Preparation, and you'll have

$\text{CN}q \text{ --- } \text{D'E} \dagger \text{IK}q \dagger \text{CD}q \dagger 2\text{NCI} \equiv \text{DM}q$:

Which were before $\equiv \text{KN}q$.

Therefore KN \equiv DM ; which is one.

In like manner resolve \square Kn.

It is certain that $\text{n}lq \dagger \text{IK}q \equiv \text{Kn}q$.

Substitute for $\text{n}lq$, by Consect. 1. Prop. 10. Lib. 1. $\text{C}lq \dagger \text{CN}q \text{ --- } 2\text{nCI}$, and you'll have

$\text{Cl}q \dagger \text{CN}q \text{ --- } 2\text{nCI} \dagger \text{IK}q \equiv \text{Kn}q$.

Substitute for $\text{Cl}q$, by the 9. lib. 1. $\text{CD}q \dagger \text{D'E}$, and you'll have $\text{CD}q \dagger \text{D'E} \dagger \text{CN}q \text{ --- } 2\text{nCI} \dagger \text{IK}q \equiv \text{Kn}q$.

Resolve

Resolve also the \square EM.

It is certain that $2CDq + 2CMq - DMq = EMq$ per 13.

lib. 1.

Then will $Clq + CNq + 2NCI + IKq = KNq$.

Substitute for Clq by the 8. lib. 1. $CDq - DIE$; then will
 $CDq - DIE + CNq + 2NCI + IKq = KNq$.

Resolve also the \square DM.

It is certain that $CMq \left\{ \begin{array}{l} 2DCM \\ 2NCI \end{array} \right\} = DMq$ per 7. lib. 1.

Substitute for CMq its value from the preparation, and you'll have

$CDq - DIE + IKq + CDq + 2NCI = DMq$;

Which before were $= KNq$.

Therefore $KN = DM$; which is one.

In like manner resolve the \square Kn.

It is certain that $nIq + IKq = Knq$.

Substitute for nIq by *Consect.* 1. *Prop.* 10. lib. 1.

$Clq + CNq - 2NCI$, and you'll have

$Clq + CNq - 2NCI + IKq = Knq$.

Substitute for Clq per 8. lib. 1. $CDq - DIE$, and you'll have

$CDq - DIE + CNq - 2NCI + IKq = Knq$.

Resolve also \square EM.

It is certain that $2CDq + 2CMq - DMq = EMq$ per 13. 1.

Substitute the value of DMq first found above, and you'll have

$CDq + CMq - 2NCI = EMq$.

Substitute for CMq the value as in the preparation, and you'll have

$CDq + CNq + DIE - 2NCI + IKq = EMq$;

Which were before $= Knq$.

Therefore $Kn = EM$; which is the other.

S H C O L I U M II.

HENCE you have the common mechanical ways of describing the ellipsis and hyperbola about their given axes; and the ellipsis, if the *Foci* N, N , (*Fig. 129. n. 1.*) are given, or found according to *Consect. 3. Prop. 7.* and having therein stuck or fixed two pins, put over them a thread NF_n tyed both ends together precisely of the length you design the greater ax DE to be of, and having put your pencil or pen in that Δ -string draw it round, always keeping it equally extended or tight. Now because the parts or portions of the thread remain always equal to the whole ax DE , what we proposed is evident by the present *Prop.* which may also be very elegantly described by a certain sort of Compasses, a description whereof *Swenterus* gives us in his *Delic. Physico-Math. Part. 2. Prop. 20.* which may be also done by a sort of organical Mechanism, by the help of two rulers moveable in the *Foci* GN and Hn (*n. 2.*) and equal to the transverse ax DE , and fastned above by a transverse ruler GH equal to the distance of the *Foci*, as may appear from the Figure. For if the style F be moved round within the fissures of the cross rulers Hn and GN the curve thereby described will be an ellipsis from the property we have just now demonstrated of it, which it hath in every point F . For the triangles HGN and NHn , which have one common side HN , and the others equal by construction, are equal one to another, and consequently the angles FHN and FNH equal, so also the legs HF and FN , and so likewise FN and F_n together are equal to $Hn = DE$; which is the very property of the ellipse we are now treating of. But *Van Schooten*, who taught us this delineation, hints, that, if thro' the middle point i of the line HN you draw the line IFL , it will touch the ellipsis in the point F ; for since the angles IFH and IFN are equal, by what we have just now said, the vertical angle LF_n of the one IFH , will be necessarily equal to the other IFN : But this equality of the angles, made by the line KL drawn thro' F , with both those drawn from the centres, is here a sign of contact, as is in the circle the equality of the angles with a line drawn from its one centre. So that after this way you may draw a tangent thro' any given point F of the

the ellipsis without this organical apparatus of Rulers; viz. if, having drawn from both the Focus's thro' the given point F the right lines nH , NG equal to the *Latus Transversum* DE , you bisect HN in I and draw IFL : Or if the line that connects the extremes GH be produced to K , and you draw thence KFL , viz. in that case where GH and Nn are not parallel; otherwise a line drawn thro' the point F parallel to them would be the tangent sought.

As to the hyperbola, there is a mechanick method of drawing that also, not unlike the others, from a like property in that, communicated by the same *Van Schooten*, viz. If having found the Focus's N and n (*Fig. 129. n. 3.*) you tie a thread NFO in the Focus N and at the end of the ruler nO of the length of the transverse ax DE ; then putting in a pen or the moveable leg of a pair of compasses (nor would it be difficult to accommodate the practice we before made use of to this also) draw or move it within the thread NFO from O to E , so that the part of the thread NO may always keep close to the ruler as if it were glued to it. For if we call the length of the thread X , and the transverse ax ob as above, the ruler nO will be, by the Hypoth. $= X \mp ob$. Make now the part of the thread $OF = \frac{1}{2} X$, the remainder or other part will be $NF = \frac{1}{2} X$ and $nF = \frac{1}{2} X \mp ob$, and the difference between FN and Fn , $= ob$. Make $OF = \frac{3}{4} X$, then will FN be $\frac{1}{4} X$ and $Fn = \frac{1}{4} X \mp ob$, the difference still remaining ob and so *ad infinitum*. In short, since the difference of the whole thread and of the whole ruler is ob , and in drawing them, the same OF is taken from both, there will always be the same difference of the remainders. Hence also assuming at pleasure the points N and n you may describe hyperbola's so, the thread NFO be shorter than the ruler nFO : For if it were equal there would be described a right line perpendicular to Nn , thro' the middle point C .

There yet remains one method of describing hyperbola's and ellipses in *Plano*, by finding the several points without the help or Apparatus of any threads or instruments, viz. in the ellipsis, having given or assumed the transverse axis DE and the Foci N and n (*Fig. 130. n. 1.*) if from N at any arbitrary distance, but not greater than half the transverse ax NF , you make an arch, and keeping the same opening of the compasses

passes you cut off, from the transverse ax, EG, and then, taking the remaining interval GD, from n you make another arch cutting the former in F, and so you will have one point of the ellipse, and after the same way you may have innumerable others, $f, f, f, \&c.$

In like manner to delineate the hyperbola, having given or assumed the transverse ax DE and the *Focus's* N and n ($n. 2.$) if from N at any arbitrary distance NF you strike an arch, and keeping the same aperture of the compasses from the diameter continued, you cut off EG, and then at the interval GD from n make another arch cutting the former in F, you will have one point of the hyperbola, and after the same way innumerable others, $f, f, \&c.$

Proposition IX.

IF the secondary ax, or conjugate diameter of the hyperbola AB (Fig. 131.) be applied parallel to the vertex E, so that it may touch the hyperbola, and OE, EP are equal like BC and AC, and from the centre C you draw thro' O and P right lines running on ad infinitum, and lastly QR parallel to the Tangent OP; you'll have the following:

CONSECTARYS.

I. **T**HE parts QG and HR intercepted between the curve and those right lines CQ, CR will be equal; for by reason of the similitude of the $\triangle \triangle$ CEP and CFR as also CEO, CFQ as CE is to EO (and EP) so will CF be to FQ and FR, and consequently these will be equal; and so taking away the semiordinates FG and FH which are also equal, the remainders GQ and HR will be also equal, and consequently the $\square \square$ QGR, GRH, $\&c.$ all equal among themselves: Which we had already deduced before in *Consect. 2.* and 3. Def. 7.

II. The rectangle QGR will be $= \square$ EO or EP $= \frac{ovcd \text{ i.e.}}{4}$
(as Apollonius speaks) to the fourth part of the figure: For by reason

reason of the similitude of the $\triangle \triangle CEO, CFQ$, CE will be to EO as CF to FQ: *i. e.*

as the $\square CE$ to the $\square EO$

i. e. as (by *Conf* 2. 7.) the *Lat. Transv.*

to the *Lat. Rect.*

i. e. (by the 7. *Prop.*) as the $\square DFE$ to the $\square FG$

} so the $\square CF$
to the $\square FQ$

But now if from the $\square CF$ you take the $\square DFE$, there will remain the $\square CE$, by *Prop.* 9. *lib.* 1. and if from the $\square FQ$ you take the $\square FG$ there will remain the $\square QGR$, by *Prop.* 8. *lib.* 1. wherefore that remaining $\square CE$ to this remaining $\square QGR$ will be, as was the whole square CF to the whole square FQ, by *Prop.* 26. *lib.* 1. *i. e.* as was the $\square CE$ to the $\square EO$; consequently the $\square QGR$ and the square EO (to which the same square CE bears the same proportion) will be equal among themselves.

III. Since this is also after the same manner certain of any other rectangle *ggr* or *grh*, &c. it follows that all such rectangles are equal among themselves.

IV. Wherefore it is most evident, since the lines FR, *fr*, &c. and so GR and *gr* grow so much the longer, by how much the more remote they are from the vertex E; that on the contrary the lines QG and *qg* must necessarily so much the more decrease and grow shorter, and consequently the right line CQ approach so much nearer and nearer to the curve EG.

V. But that they can never meet or coincide altho' produced *ad infinitum* will thus appear; if it were possible there could be any concurrence or meeting, so that the point G and Q or *g* and *q* could any where coincide, it would follow from *Consect.* 2. that as the $\square DFE$ to the square FG so the square CF to the square FQ *i. e.* to the same square FG; and so that the $\square DFE$ would be $= \square CF$; which is absurd by *Prop.* 9. *lib.* 1. so that now it is evident that the lines COQ and CPR drawn according to *Consect.* 1. are really Asymptotes *i. e.* they will never (α) coincide (*viz.* with the curve of the hyperbola) as Apollonius has named them.

(α) Apoll.
Prop. 1. *lib.* 2.

R

VI. Having

VI. Having drawn the right lines from G and g parallel to both the asymptotes, *viz.* GS and gs and likewise GT and gt , the rectangles TGS and tgs will be (α) equal among themselves. For by reason of the

(α) Apollon.
Prop. 12. lib. 2.

similitude of the $\triangle TQG$ and tqg , *first*, TG will be to QG as tg to qg ; and, by reason of the equality of the $\square QGR$ and qgr , *secondly*, QG will be to gr reciprocally as qg to GR , by Prop 19. lib. 1. and by reason of the similitude of the $\triangle SGR$ and sgr , *thirdly*, as gr to gs so GR to GS , wherefore (since in two series

1. 2. 3.

as TG to QG to gr to gs

so tg to qg to GR to GS)

you'll have *ex æquo* or by proportion of equality as TG to gs so tg to GS , by Prop. 24. lib. 1. Therefore, by Prop. 17. of the same, the \square of TG into $GS = \square$ of tg into gs . Q. E. D.

SCHOLIUM.

Hence, lastly, we have a new genesis of the hyperbola in *Plano* about its given diameters from the speculations of

(β) De Witt
Elem. Curv. lib.
1. cap. 2. prop. 3.

(β) De Witt; if, *viz.* having drawn the lines AB and EF cross one another at pleasure (Fig. 132) to the angle BCF you conform the moveable angle BCD (acd being to be delineated in the opposite hyperbola equal to the contiguous ACD) one of whose legs is conceived to be indefinitely extended, but the other CD of any arbitrary length; and to the end of it D apply the slit of a moveable ruler GD about the point G at any arbitrary interval GD (but yet parallel to the leg CB in this first station) and so carrying together along with it the moveable angle BCD about the line ECF , but so that the leg CD may always remain fast to it, and the other CB be intersected in its progress by the ruler GDH , *e. g.* in b or β . This point of intersection, thus continually moved on, will describe the curve $bG\beta$, which we thus prove to be an hyperbola: Because the ruler GDH turning about the pole G , and carried from D *e. g.* to d or δ cuts the leg of the moveable angle CB brought

brought to the situation cb or $\gamma\beta$, and in the mean while remaining always parallel to it self; and having drawn from the points of intersection b and β and G the lines GI , bK and $\beta\kappa$ parallel to the ruler CF , because *e. g.* in the second station, having taken the common quantity cD from the equal ones CD and cd , the remainders Cc and Dd are equal, and by reason of the similitude of the $\triangle \triangle dcb$ and dDG ,

$$\begin{array}{l} \text{as } Dd \} \text{ to } DG, \text{ so } dc \} \text{ to } cb; \\ \text{i. e. } Cc \} \quad \quad \text{i. e. } DC \} \\ \text{or } bK \} \quad \quad \text{or } GI \} \end{array}$$

the rectangle of Kb into bc will be \equiv \square of DG into GI , by *Prop. 18. lib. 1.* and in like manner, when in the third station having added the common line $D\gamma$ to the equal ones CD and $\gamma\delta$, the whole lines $D\delta$ and $C\gamma$ are equal, and, by reason of the similitude of the $\triangle \triangle \beta\gamma\delta$ and $GD\delta$

$$\begin{array}{l} \text{as } D\delta \} \text{ is to } DG \text{ so is } \gamma\delta \} \text{ to } \gamma\beta; \\ \text{i. e. } C\gamma \} \quad \quad \text{i. e. } DC \} \\ \text{or } \beta\kappa \} \quad \quad \text{or } GI \} \end{array}$$

the \square of $\kappa\beta$ into $\beta\gamma \equiv \square$ of DG into GI , by the same 18. *Prop.* Wherefore the three points b , G , β , (and so all the others that may be determined the same way) are in the hyperbola, whose asymptotes are CB and CF and its centre C , &c. by the present *Prop. Consect. 6.* Q. E. D.

You may also determine innumerable points of this curve separately without the motion we have now prescribed, *viz.* as the point a in the opposite hyperbola, if thro' any assumed point c in the asymptote CE you draw a parallel to the other asymptote CA , and having made cd equal to CD , from G thro' d draw Gda , and so in others.

C H A P. II.

Of Parabolical, Hyperbolical and Elliptical Spaces.

Proposition X.

(a) Archim.
de Quadratur.
Parab. Prop.
17. and 24.

THE (a) Parabolick Space (i. e. in Fig. 133: that comprehended under the right line GH and the parabola GEH) is to a circumscribing Parallelogram GK, as 4 to 6 (or 2 to 3) but to an inscribed \triangle GEH as 4 to 3.

Demonstration.

Suppose FH divided first into two then into four equal parts, and draw parallel to the ax EF the lines *ef*, *cf*, &c. dividing also EF into four parts, the first *fg* will be 3, the second 2, the third 1, by Prop. 34. lib. 1. but as *ef* is to *ge* so is *ge* to *be*, by Consect. 1. Prop. 4. Therefore *be* in the diameter EF is $\equiv 0$, in the first *ef* it is $\equiv \frac{1}{4}$ (for as *ef*, 4, to *ge*, 1, so *ge*, 1, to *be*, $\frac{1}{4}$) in the second *cf* a portion of *be* is $\equiv \frac{1}{4}$, in the third to $\frac{3}{4}$, and so the portions *eb* in the trilinear figure EbHK make a series in a duplicate arithmetical progression, viz. 1, 4, 9, 16: After the same manner, if the parts *Ef*, &c. are bisected, you'll find the portions *eb* in the external trilinear figure to make this series of numbers $\frac{1}{8}$, $\frac{4}{8}$, $\frac{9}{8}$, $\frac{16}{8}$, $\frac{25}{8}$, $\frac{36}{8}$, $\frac{49}{8}$, $\frac{64}{8}$, and so onwards. Wherefore since the portions *eb* or the indivisibles of the trilinear space circumscribed about the parabola are always in a duplicate arithmetical progression: the sum of them all will be to the sum of as many indivisibles of the parallelogram FK, equal to the line KH, i. e. the trilinear space it self to this parallelogram as 1 to 3, by Consect. 10. Prop. 21. lib. 1. Wherefore the semi-parabola FEbH will be as 2, and the \triangle FEH as $1\frac{1}{2}$; therefore the whole parabola as 4, and the whole \triangle GEH as 3, and the whole parallelogram GK as 6. Q E. D.

CON-

CONSECTARY I.

IT is evident (α) that in the first division, the second line fb (*i. e.* that drawn from the middle of the base FH) is three such parts whereof FE is 4; for eb is $\frac{1}{4}$ *i. e.* 1, therefore fb is 3.

(α) Archim.
Prop. 19. with
the Coroll.

CONSECTARY II.

IT is also evident, that this demonstration will hold of any parabolick segment.

Proposition XI.

THE Elliptical Space (α) comprehended by the Ellipsis DAEB (Fig. 127.) is to a circle described on the transverse ax DE, as the Axis Rectus or conjugate diameter AB to the transverse ax DE.

(α) Archim.
lib. de Conoid.
&c. Prop. 5.

Demonstration.

THIS is in the first place evident from the genesis of the ellipse we deduced in Schol. 1. Prop. 7. for in that deduction we shewed that FO, *i. e.* HN was to NI as AB to DE: Which since it is true of all the other indivisibles or ordinates HN and IN *ad infinitum*; it is manifest that the planes themselves constituted of these indivisibles will have the same reason among themselves, as the Axis Rectus AB to the transverse DE. Q. E. D.

CONSECTARY I.

Therefore the quadrature of the ellipse will be evident, if that of the circle be demonstrated.

CON-

CONSECTARY II.

Since a circle described on the least diameter AB will be to one described on the greater diameter DE, as AB to a third proportional by *Prop. 35. lib. 1.* it follows by vertue of the present *Prop.* that the ellipse is a mean proportional between the greater and lesser circle, *i. e.* as the ellipse is to the greater circle so is the lesser circle to it, *viz.* as AB to DE.

CONSECTARY III.

Hence you may have a double method of determining the area of an ellipse. 1. If having found the area of the greater circle, you should infer, as the greater diameter of the ellipsis to the less, so the area of the circle found to the area of the ellipse sought. 2. If having also found the area of the lesser circle, you find a mean proportional between that and the area of the greater.

S C H O L I U M.

WE may also shew the last part of the second *Consect.* thus, 1. If having described the circle EadbE (*Fig. 134.*) about the least axis of the ellipse we conceive a regular hexagon to be inscribed, and an ellipse coinciding with one end E of its transverse ax, and with the other or opposite one D to be so elevated, that with the point *d* it may perpendicularly hang over the circle, and further from all the angles of the figure inscribed in the circle you erect the perpendiculars *gG*, *bB*, &c. it is certain that the sides ED and Ed of the triangle DEd will be cut by the parallel planes FGgf, &c. into proportional parts, and that those by reason of the similitude of the \triangle FDG and fdg, and so also the other rectangles will be among themselves as the intercepted parts of the lines ID and id, CI and ci, and in infinitum, (*viz.* of how many sides soever the inscribed figure consists:) Wherefore also all the parts of the ellipse taken together will be to all the parts of the circle taken together, *i. e.* the whole ellipse to the whole circle

be to
to a
ue of
ween
reat-

s
e
.
-
t

circle as all the parts of the diameter ED or *ab*, i. e. as DE it self to AB. Q. E. D.

CONSECTARY IV.

IT is also evident that both these demonstrations of the present Prop. will be also the same in any segments of the ellipsis or circle.

Proposition XII.

ANY Hyperbolical space GEHG (Fig. 135) is to any Hyperbolick figure of equal height *gEbg* [whose *Latus Rectum* and *Transversum* are equal (as in the circle) and also equal to the *Latus Transversum* of the former DE, as the *Axis Rectus* (or conjugate) AB is to the *Latus Transversum* DE (as in the ellipsis.)

Demonstration.

By the Hypoth. and Prop. 7. and its second Consect. the \square Fg is \square DFE. Wherefore this \square DFE i. e. the \square Fg is to the \square FG as the *Latus Transversum* to the *Latus Rectum* of the hyperbola GEHG, by the same seventh Prop. i. e. (by Consect. 2. of the same) as the square of the *Latus Transvers.* DE to the square of the conjugate AB: Therefore the roots of these squares will be also proportional, viz. Fg to FG as DE to AB; and consequently (since the same is true of any other ordinates *ad infinitum*) the whole hyperbola *gEbg* will be to the whole one GEHG as DE to AB. Q. E. D.

CONSECTARY I.

Therefore having found the quadrature of such an hyperbola, whose *Latus Rectum* and *Transversum* are equal, you may have also the quadrature of any other hyperbola.

CON-

CONSECTARY II.

IT is evident that the same demonstration will hold in any other hyperbola's.

Proposition XIII.

ANY Parabolick segments upon the same base, and hyperbolic and elliptical ones described about the same conjugate (one whereof shall be a right one, the other a scalene) and constituted between the same parallels, are equal.

Demonstration.

I. It is evident of Parabola's; for both the right one GEHG, and the scalene one GCHG (*Fig. 136. n. 1.*) (for the demonstration of *Prop. 10.* will hold in both) is to a Δ inscribed in them as 4 to 3. But the triangles GEH and GCH are equal, by *Consect. 5. Def. 12. or Prop. 28. lib. 1.* Therefore the Parabola's also.

Or thus, in the right parabola GEHG every thing is the same as in 1. and 4. *Prop.* of this Book, viz. $El = eb$, $EF = ib$, the square $IK = oecc$, the $\square FG = oicc$. And because therefore in the scalene Parabola also the square FG remains $= oicc$, make $FC = n$, and find both the abscissa CE , and the \square answering to it IK .

1. For the abscissa; as FE to El so FC to CE , per

$$ib \text{ --- } eb \text{ --- } n \text{ --- } \frac{en}{i}$$

Consect. 4. Prop. 34. lib. 1.

2. For the $\square IK$; as FC to CE so $\square FG$ to $\square IK$,

$$n \text{ --- } \frac{en}{i} \text{ --- } oicc \text{ --- } F. oecc.$$

per *Prop. 4.* of this.

Therefore the $\square IK = \square IK$ and $IK = IK$, and this in any case *ad infinitum*: Therefore the one parabola is $=$ to the other. Q. E. D.

II. The

II. The business is much after the same way evident of ellipses and hyperbolas. For making all things in the ellipsis and right hyperbola (*n*. 2. and 3. *Fig.* 136.) as in *Prop.* 2, 3, 5, 7. viz. the $\square IK$ *oecd* — *eed* in the ellipsis, *oecd* + *eed* in the hyperbola, the $\square AB$ *oecd* by *Consect.* 2. *Prop.* 7. $El = eb$, $DE = ob$, &c. if in oblique ones for the *Latus Transversum* DE you put *n*, and seek the *Latus Rectum* and abscissa EA , you may by means of these also have the square IK , by *Prop.* 2. and 3.

1. For the *Latus Rectum*.

As *n* to \sqrt{oecd} so \sqrt{oecd} to $\frac{oecd}{n}$, by *Cons.* 2. 7:

2. For EA the abscissa.

As *ob* to *eb* so *n* to $\frac{en}{n} = EA$.

3. For the side *RS* \square deficient or exceeding, from *Prop.* 2. and 3.

As $\frac{n}{n}$ to $\frac{oecd}{o}$ so $\frac{en}{o}$ to $\frac{oede}{n} = RS$.

Now the abscissa multiplied by the *Lat. Rect.* | The abscissa multiplied by *RS*.

$\frac{en}{o}$ by $\frac{oecd}{n}$ gives $\square oecd$.

$\frac{en}{o}$ by $\frac{oede}{n}$ gives $\square eecd$.

The sum of these $\square \square oecd$ + | The difference of these $\square \square$
eed in the hyperb. = $\square IK$ | *oecd* — *eed* gives in the ellipsis
 by *Prop.* 2. evidently = $\square IK$ | $\square IK$ by *Prop.* 3. evidently =
 $\square IK$.

Wherefore the lines IK and IK , and the whole KL and KL will be equal; and since the same thing is evident after the same way of all other lines of this kind *ad infinitum*, the elliptical and hyperbolic segments will be so also. Q. E. D.

C H A P. III.

Of Conoids and Spheroids.

Proposition XIV.

(a) Archim.
Prop 23. and
24. (al. 26.
and 27.)

A Parablick Conoid (a) is subduple of a Cylinder, and in sesquialteran reason (a as 1 $\frac{1}{2}$) of a cone of the same base and altitude.

Demonstration.

Because in the parabola the \square AD (Fig. 137.) is to the \square SH, as BD to BH, i. e. as 3 to 1, and so to the \square TI as BD to BI, i. e. as 3 to 2, by Prop. 4. of this; it is evident that these squares of SH and TI and AD and consequently of the whole lines also Sb, Ti, AC, and the circles answering to them will be in arithmetical progression, 1, 2, 3; and moreover if there are new Bisections in infinitum, as the abscissa's so also the squares and circles of the ordinates, by virtue of the aforesaid fourth Prop. will always be in arithmetical Progression 1, 2, 3, 4, 5, 6, &c. It is evident that an infinite series of circles in the conoid, consider'd as its indivisibles, will be to a series of as many circles equal to the greatest AC, i. e. the conoid to the cylinder AF as 1 to 2, or as 1 $\frac{1}{2}$ to 3, by Coroll. 9. Prop. 21. or Coroll. 4. Prop. 16. lib. 1. but to the same cylinder AF the inscribed cone ABC is as 1 to 3, by Prop. 38. lib. 1. therefore the cylinder, conoid and cone are as 3, 1 $\frac{1}{2}$ and 1. Q.E. D.

Proposition XV.

(a) Archim.
29. and 30.
(al. 32. and 33.)

THE half of (a) any Spheroid, or any other segment of it is in subsesquialteran proportion to the cylinder, and double of the cone having the same base and altitude.

Demonstr.

Demonstration.

Having divided the altitude BD (*Fig. 138.*) *e. g.* into three equal parts, because in the ellipse as well as in the circle the square of AD is to the square of SH as the \square GDB to the \square GHB, *i. e.* as 9 to 5, and so to the square TI as 9 to 8, by *Consect. 1. Prop. 5.* of this; and in like manner if you make new bisections, the squares (and consequently the circles) of the ordinates go on or decrease by a progression of odd numbers, as 36, 35, 32, 27, 20, 11, and so *ad infinitum*, the bisections being continued on; as we have shewn in the sphere and circumscribed cylinder *Prop. 39. lib. 1.* and it will necessarily follow here also (by virtue of *Consect. 12. Prop. 21.*) that the whole cylinder will be to the inscribed segment of the spheroid, as 3 to 2; and since the same cylinder is to the cone ABC as 3 to 1, also the segment of the spheroid will be to the cone as 2 to 1. Q. E. D.

Proposition XVI.

AN hyperbolic Conoid (*a*) is to a cone of the same base and altitude, as the aggregate of the ax of the hyperbola that forms it and half the Latus Transversum, to the aggregate of the said axis and Latus Transversum.

(*a*) Archim.
Prop. 27. and 28. (al. 30. and 31.)

Demonstration, containing also the Invention of this Proportion.

Make (in *Fig. 139.*) CE = *a*, EF = *b*, OE = *c*; then will CF = *a* + *b*. Since therefore,

$$\text{as CE to OE so CF to FQ}$$

$$a \text{ --- } c \text{ --- } a + b \text{ --- } \frac{ac + bc}{a}$$

$$\text{the } \square \text{ EO will } = cc \text{ and } \square \text{ FQ } = \frac{aacc + 2abcc + bbcc}{a}$$

But as these squares so also are the circles of the lines EO and FQ to one another, by *Prop. 32. lib. 1.* and so the cone COP

will be as $\frac{acc}{3}$, and the cone CQR as $\frac{acc}{3} + \frac{bcc}{3} + \frac{bbcc}{3} + \frac{b^3cc}{3}$

(viz. by multiplying the third part of the altitude CF by the base FQ:) Having therefore subtracted the cone COP from the cone CQR, there will remain the truncated cone QOPR $\frac{bcc}{3} + \frac{bbcc}{3} + \frac{b^3cc}{3}$, and from this solid truncated cone having

further subtracted the hollow truncated cone, which the space EHRP produced in the genesis of the conoid (and which according to *Consect. 2. Definit. 9.* is as $\frac{bcc}{3}$) there will remain the hyperbolical conoid $\frac{bbcc}{3} + \frac{b^3cc}{3}$, i. e. (by substituting now

the values of the ax or abscissa EF, and of half the *Lat. Transv.* EC, and of the conjugate diam. OP, &c. found in the demonstrations of the preceding Chapter, viz. $\frac{ob}{2}$ for a , $\frac{eb}{2}$ for

b , and \sqrt{ooed} for c or $ooed$ for cc) the hyperbolical conoid will come out $\frac{2eebocd}{3} + \frac{4e^3bcd}{3}$ i. e. $\frac{6eebocd}{3} + \frac{4e^3bcd}{3}$. But

the cone GEH (multiplying the third part of EF into the \square GH, i. e. $\frac{1}{3}eb$ into $4oecd + 4eecd$) is as $\frac{4eebocd}{3} + \frac{4e^3bcd}{3}$.

Therefore the conoid is to the cone as $\frac{6eebocd}{3} + \frac{4e^3bcd}{3}$ to $\frac{4eebocd}{3} + \frac{4e^3bcd}{3}$, i. e. (dividing on both sides by $4eecd$) as $\frac{1}{2}ob + eb$ to $ob + eb$. Which was to be found and demonstrated.

S C H O L I U M.

IF any one had rather proceed herein by indivisibles, as in the precedent Prop. having divided the ax EF (*Fig. 140.*) again into three equal parts, and assuming the values of the lines determined in the hyperbola, viz. $\frac{eb}{b}$ for the abscissa EF, $\frac{ob}{b}$ for the transverse ax, $\frac{ocd}{b}$ for the *Latus Rectum*, $\frac{oecd + eecd}{b}$

for the square of the semiordinate FG, &c. the lowest and greatest circle of the diameter HG will be as $\frac{oecd + eecd}{b}$, and, if you make

as the *Latus Transv.* to the *Latus Rectum*, so the \square DfE

$$\frac{ob}{\quad} \quad \frac{ocd}{b}$$

made of $ob + \frac{2}{3}eb$ into $\frac{2}{3}eb$ (i. e. $\frac{2}{3}oebb + \frac{4}{9}eebb$) to a fourth;
 there will come out $\frac{2}{3}oced + \frac{4}{9}eecd$ for the second circle of the
 diam. bg ; and by the same inference (as ob to ocd so $ob + \frac{1}{3}eb$

$$\frac{b}{b}$$

into $\frac{1}{3}eb$ to a fourth) for the third circle of the diameter hc
 $\frac{1}{3}oced + \frac{1}{9}eecd$; so that these indivisibles [for which here and
 in the precedent also the partial circumscribed cylinders may
 be assumed] proceed in a double series of numbers, the first in
 a simple arithmetical progression 3, 2, 1, the latter in a du-
 plicate Arithmetical progression of squares 9, 4, 1; and the
 same if you make further new bisections, will necessarily hap-
 pen *ad Infinitum*, (the former numbers *e. g.* in the first bise-
 ction will be $\frac{6}{36} \frac{2}{36} \frac{2}{36} \frac{2}{36} \frac{1}{36} ocad$ the latter $\frac{36}{36} \frac{25}{36} \frac{16}{36} \frac{9}{36} \frac{4}{36} \frac{1}{36} eecd$, &c.)
 it is manifest from the consecutaries of *Prop. 21. lib. 1.* that the
 whole cylinder HK will in like manner be expressed by a
 double series of parts answering, in numbers to the indivisibles
 of the conoid made by any bisection, but in magnitude to
 the greatest of them all, and in the sum of its first series of
 parts will be to the sum of the first in the conoid, both being
 infinite, as 2 to 1 or 3 to $1 \frac{1}{2} ocad$, by *Consect. 9.* of the
 said *Prop. 21.* and the sum of its latter to the sum of the
 former in the conoid will be as 3 to 1 $eecd$ and so the whole
 cylinder to the whole conoid as $3 ocad + 3 eecd$ to $1 \frac{1}{2} ocad +$
 $eecd$ i. e. (dividing by ecd) as $3 o + 3 e$ to $1 \frac{1}{2} o + e$ i. e. mul-
 tiplying both sides by b as $3 ob + 3 eb$ to $1 \frac{1}{2} ob + eb$; and
 consequently the cone (which is $\frac{1}{3}$ of the cylinder) to the co-
 noid as $ob + eb$ to $1 \frac{1}{2} ob + eb$. Q. E. D.

CONSECTARY.

Hence also appears the proportion of the hyperbolick co-
 noid to a cylinder of the same base and altitude, which
 we did not express in the *Prop. viz.* as the aggregate of the
 ax and half the *Latus Transversum* to triple the aggregate of
 the said ax and *Latus Transversum*.

CHAP.

C H A P. IV.

Of Spiral Lines and Spaces.

Proposition XVII.

(a) Archim.
Prop. 24. de Spi-
ral.

THE (a) first spiral space is subtriple of the first circle, i. e. as 1 to 3.

Demonstration.

Having divided the circumference of the circle into (Fig. 141. n. 1.) three equal parts by lines drawn from the initial point, beginning from the first line BA, the line BC will be as 1, BD as 2, BA as 3, by *Consect. 1. Def. 12.* of this book, and consequently the sectors circumscribed about the spiral will be CBc as 1, DBd as 4, ABa as 9, by *Prop. 32. lib. 1.* and in like manner, if you make new bisections, the lines drawn from the point B to the spiral, will be 1, 2, 3, 4, 5, 6; but the circumscrib'd sectors, 1, 4, 9, 16, 25, 36; and so the circumscrib'd partial sectors *ad infinitum* will proceed in an order of squares, there being always as many sectors in the circle equal to the greatest of them. Therefore all the sectors that can be circumscrib'd *ad infinitum* about the spiral space, i. e. the spiral space it self (in which at last they end) to so many equal to the greatest, i. e. to the circle, is as 1 to 3, by *Consect. 10. Prop. 21. lib. 1.* Q. E. D.

CONSECTARY I.

Since the first circle is to the second as 1 to 4. (i. e. as 3 to 12) by *Def. 12.* of this, and *Prop. 31. lib. 1.* and the first spiral space to the first circle as 1 to 3 by the present *Prop.* the same spiral space will be to the second circle as 1 to 12; and to the third by a like inference as 1 to 27, to the fourth as 1 to 48, &c.

EON.

CONSECTARY II.

THE first spiral line is equal to half the circumference of the first circle. For the lines or radii of the sectors, and consequently their peripheries or arches proceed in a simple arithmetical reason, as 1, 2, 3, 4, 5, 6, &c. while in the mean time the whole periphery of the circle contains so many arches equal to the greatest. Therefore the whole periphery of the circle is to an infinite series of circumscrib'd arches, *i. e.* to the spiral line it self, as 2 to 1, by *Consect. 9. Prop. 21. lib. 1.*

Proposition XVIII.

THE whole spiral (a) space comprehended under the second right line EA and the second spiral EGLA (see Fig. 141. n. 2.) is to the second circle as 7. to 12. (a) Archim.
Prop. 25.

Demonstration.

For having divided the circumference of the circle first into three equal parts, there will be drawn to the second spiral four right lines BE, BG, BI and BA being as 3, 4, 5, 6, and but only three sectors circumscrib'd, *viz* GBg, IBi and ABa, which proceed according to the squares of the three latter lines, *viz* 16, 25, 36, so that the sum is 77, while the sum of three equal to the greatest is 108, and so the one to the other (dividing both sides by 9) as 12 to 8 $\frac{1}{3}$. Having moreover bisected the arches and parts of the line BE, so that that shall be 6, the second BF will be 7, and so the other five 8, 9, 10, 11, 12; and the sectors answering to them (excepting the first) 49, 64, 81, 100, 121, 144, so that their sum shall be 559, while the sum of six equal to the greatest, *i. e.* the whole circle is 864, and so one to the other (dividing both by 72) as 12 to 7 $\frac{1}{2}$. In the other bisection of the arches and the parts of the line BE, so that the one shall be 12, the second 13, &c. to the thirteenth BA which will be 24, the sum of twelve sectors will be found to be 4250; and the sum of

as

as many equal to the greatest 6912, and so the one to the other (dividing both sides by 576) as 12 to $7\frac{218}{176}$ f. 176. Therefore the proportion will be

- I. In the first case 12 to $7 + 1 + \frac{1}{2} + \frac{1}{18}$ viz. $\frac{4}{72}$.
 II. In the second case 12 to $7 + \frac{1}{2} + \frac{1}{4} + \frac{1}{72}$ viz. $\frac{4}{288}$.
 III. In the third case 12 to $7 + \frac{1}{4} + \frac{1}{8} + \frac{1}{288}$ &c.

The first and second fractions thus decreasing by $\frac{1}{2}$ the latter by $\frac{1}{4}$. Wherefore the proportion of the second circle to the second spiral space will be as

$$12 \text{ to } 7 + 1 + \frac{1}{2} + \frac{1}{18} \\ \text{---} \frac{1}{2} \text{---} \frac{1}{4} \text{---} \frac{3}{72} \\ \text{---} \frac{1}{4} \text{ &c. ---} \frac{1}{8} \text{ &c. ---} \frac{3}{288} \text{ &c.}$$

By virtue of *Consect.* 3. and 8. $\square \circ \square \circ$

Prop. 21. *lib.* 1.

i. e. as 12 to 7. Q. E. D.

CONSECTARY I.

BEcause the second circle is to the first spiral space as 12 to 1, by *Consect.* 1. of the preceding *Prop.* and to the second spiral space as 12 to 7, by the present. it will be to the second space without the first (viz. BCDEAIGE) as 12 to 6 *i. e.* as 2 to 1.

CONSECTARY II.

Therefore the second space separately to the first is as 6 to 1.

CONSECTARY III.

Since in the trisection of both these circles, first and second, there arise six lines, and as many sectors, viz. three lines BC, BD, BE, *i. e.* 1, 2, 3, to which there answer three arches in the same progression within the second circle, and also as many equal to its greatest; therefore the sum of all the unequal arches will be 21, but the sum of the equal ones of both circles (each of which in the first are equivalent to 3, in the second to 6) will be 27. Wherefore the sum of both the Peripheries to the sum of all the circumscrib'd arches will be as

27 to 21, *i. e.* (dividing both sides by 9) as 3 to 2 $\frac{1}{3}$. Moreover bisecting the arches of the circles and the parts of the line BA, there will arise six circumscribed unequal arches within the first circle, which are as 1, 2, 3, 4, 5, 6, and as many within the second 7, 8, 9, 10, 11, 12; the sum of all which is 78, while the sum of as many equal ones on both sides is 108. Wherefore the one will be to the other, *i. e.* the sum of both the peripheries to twelve circumscribed arches taken together, is now as 108 to 78, *i. e.* (dividing both sides by 36) as 3 to 2 $\frac{1}{6}$. And making yet another bisection, the proportion will be found to be as 3 to 2 $\frac{1}{12}$, &c. and hence at length may be evidently inferr'd; that the sum of both the peripheries will be to the sum of all the arches circumscribable *ad infinitum*, *i. e.* to the whole helix as

$$3 \text{ to } 2 + \frac{1}{3}$$

$$\frac{1}{6}$$

$$\frac{1}{12}$$

&c. = 0. that is, as 3 to 2. Q. E. D.

CONSECTARY IV.

Therefore, since the periphery of the second circle is double of the first, that alone will be equal to the whole spiral.

CONSECTARY V.

Therefore, if the periphery of the second circle be 2, the periphery of the first will be 1, and the first spiral line $\frac{1}{2}$ by *Consect. 2.* of the anteced. *Prop.* wherefore the second spiral alone will be $1\frac{1}{2}$, and so the periphery of the second circle alone will be to the second spiral alone as 2 to $1\frac{1}{2}$ *i. e.* as 4 to 3; and to the first alone as 4 to 1.

SCHOLIUM I.

BUT as *Consect. 4.* may be also deduced after another way, *viz.* by comparing only the arches of the second circle with the correspondent circumscripts, but considering them as taken twice (because that circle is twice turned round while the whole helix or spiral is described) and finding in the first

T

trisection

trisection the proportion of double the second periphery to all the circumscripts as 12 to 7; and in the succeeding bisection as 12 to $6\frac{1}{2}$; in the second bisection as 12 to $6\frac{1}{4}$, &c. and at length by inferring, that the second periphery is double of all the arches circumscribable about the whole helix *ad infinitum*, that is to the helix it self.

as 12 to $6\frac{1}{4}$

$\frac{12}{6\frac{1}{4}} \approx 0$. i. e. as 12 to 6;

and consequently the simple second periphery will be to the whole helix as 6 to 6: Thus the 5. *Consect.* may be separately had after the same manner, if instead of the first trisection, you only bisection; (*vid. Fig. 141. n. 3.*) for so in the first bisection the arches circumscribed about the second spiral line would be separately two semi-circles *Dd*, 3 and *Aa*, 4, (for as the line *BC* is one, *BE*, 2, *BD*, 3, *BA*, 4; so the arch described by the radius *BD* is 3 and described by the radius *BA* = 4,) and their sum 7; while the sum of two equal to the greatest is 8. In the second bisection (when *BE* is 4) *BF* and its arch is made 5, the arch *BD* 6, the arch *BG* 7, the arch *BA* 8, the sum 26; while the sum of so many quadrants equal to the greatest is 32. Thus in the third bisection the sum of eight Octants circumscrib'd about the second helix will be found to be 100, the sum of so many = to the greatest 128, &c. Wherefore the periphery of the second circle in the first case will be to the arches circumscrib'd about the second helix as 4 to $3\frac{1}{4}$; in the second as 4 to $3\frac{1}{8}$; in the third as 4 to $3\frac{1}{16}$, &c. and so to all the arches circumscribable *in infinitum*, i. e. to the second helix it self as

4 to $3\frac{1}{16}$

$\frac{4}{3\frac{1}{16}} \approx 0$. i. e. as 4 to 3. Q. E. D.

By the same method you may easily find the proportion of the third circle to the third spiral space, and of that periphery either to the whole spiral, or separately to the third, as will be evident to any one who tries.

I. For the third spiral space.

(Fig. 142)

BC 1 BF 4 BI 7 | 49
BD 2 BG 5 BK 8 | 64
BE 3 BH 6 BA 9 | 81 are the three first sectors
circumscrib'd about the parts of the third helix. The sum of
these three sectors is 194; and the sum of so many equal to
the greatest 243. Therefore the first proportion of the one
sum to the other will be as 243 to 194, *i. e.* (dividing both
sides by 9) as 27 to 21 $\frac{1}{3}$.

In the first bisection there will be seven lines :

BH 12,	BL 13	169
	BI 14	196
	BM 15	225
	BK 16	256
	BN 17	289
	BA 18	324

Sectors circumscribed about the
parts of the third helix.

Sum 1 1459; while in the mean time the sum
of as many equal to the greatest is 944, and so the second pro-
portion as 1944 to 1459 *i. e.* (dividing both sides by 72) as
27 to 20 $\frac{19}{72}$.

In the second Bisection there will be thirteen lines, *viz.* BH
24, the rest 25, 26, &c. but the sum of the sectors, *i. e.* of
the square numbers answering to the twelve latter will be
found to be 11306; while in the mean time the sum of as ma-
ny equal to the greatest will be 15552, so that you will have
the third proportion of this sum to the other, *viz.* as 15552 to
11306, *i. e.* (dividing both sides by 576) as 27 to 19 $\frac{362}{576}$.

Therefore the 1. proportion will be as 27 to 19 $\frac{2}{9}$ $\frac{1}{9}$ *i. e.*

II. — as 27 to 19 $\frac{1}{2}$ $\frac{1}{18}$ *i. e.*

III. — as 27 to 19 $\frac{1}{4}$ $\frac{1}{72}$ *i. e.*
to 19 $\frac{1}{2}$ $\frac{1}{8}$ $\frac{1}{288}$

Therefore the proportion of the third circle to the third spi-
ral space will be

T 2

as

as 27 to 19 $\frac{1}{2} + \frac{1}{2} + \frac{1}{2}$

$$\frac{1}{2} - \frac{1}{4} - \frac{3}{72} \text{ i. e. as 27 to 19.}$$

$$\frac{1}{2} \&c. - \frac{1}{8} \&c. - \frac{3}{288} \&c.$$

$$\equiv 0. \quad \equiv 0. \quad \equiv 0. \quad \text{Q. E. D.}$$

II. For the third spiral line.

If instead of the first trisection (as less commodious for the end proposed) you make use here also, as before, of bisection in the same figure, there will come out six lines from the point B to the helix, viz. Bm, 1, BE, 2, Bn, 3, BH, 4, Bo, 5, BA, 6; to which there answer as many semicircular arches in the same progression, and to the greatest of the two as many equal to 2, 4, 6; so that the sum of the unequal ones is 21, and of the equal ones 24, and so the proportion of three peripheries together to all the circumscripts together will be as 24 to 21 (and dividing both by 6) as 4 to 3 $\frac{1}{2}$. In the second bisection the twelve unequal lines and arches make the sum 78, and as many equal to the greatest of the four will give the sum 96; so that the second proportion will be 96 to 78, i. e. (dividing both sides by 24) 4 to 3 $\frac{1}{2}$. In the third bisection the proportion will come out as 384 to 300, i. e. (dividing both sides by 96) as 4 to 3 $\frac{1}{2}$, &c. Therefore the proportion of the three circles together to the whole Helix will be as 4 to 3 $\frac{1}{2}$.

$$\frac{1}{2} \&c. \equiv 0. \text{ i. e. as 4 to 3 or 12 to 9.}$$

Q. E. D.

CONSECTARY VI.

NOW, if the periphery of the first circle be made 2, the second will be 4, the third 6, and consequently the sum 12; it will be manifest that the third periphery separately will be to the whole helix as 6 to 9, i. e. as 2 to 3.

CON:

CONSECTARY VII.

AND because the second periphery (which is 4) is equal to the first and second helix together, by the above *Consect.* 4. the remaining third spiral will be 5, and so the proportion of the third periphery to it as 6 to 5.

CONSECTARY VIII.

WHerefore the proportions of each of the peripheries to their correspondent spirals will be in a progression of ordinal numbers, *viz.* so that the latter of every two will denote the periphery of a circle, and the former an inscribed spiral; and consequently the spiral lines will be in an arithmetical progression of odd numbers, and the peripheries of the circles in a progression of even ones.

- 1 ——— The first Spiral,
- 2 ——— The first Periphery,
- 3 ——— The second Spiral,
- 4 ——— The second Periphery,
- 5 ——— The third Spiral,
- 6 &c. — The third Periphery, &c.

S H C O L I U M II.

THE seventh Consectary may also be easily deduced separately this way: In the first bisection the line BA and its periphery is 6, the line Bo and its periphery 5, the sum of the circumscribed Peripheries 11; the sum of as many equal to the greatest 12. Therefore the periphery of the third circle will be to the two circumscripts as 12 to 11, *i. e.* as 6 to 5 $\frac{1}{2}$. In the second bisection the four circumscribed quadrants will be 12, 11, 10, 9, their sum 42; and the sum of four equal to the greatest, *i. e.* the periphery of the third circle 48. Therefore the proportion is now as 48 to 42, *i. e.* (dividing both sides by 6) as 8 to 7. Thus you will have the third proportion as 192 to 168, *i. e.* (dividing both sides by 32) as 6 to 5 $\frac{1}{2}$. Wherefore the proportion of the third periphery to the third helix or spiral is

as

as 6 to $5 + \frac{1}{2}$

$$\begin{array}{r} \frac{1}{2} \\ \hline \frac{1}{4} \\ \hline \frac{1}{8} \end{array} \text{ &c.}$$

= 0. i. e. as 6 to 5. Q. E. D.

CONSECTARY IX.

AS Consect. 8. supplies us with a rule to determine the proportion of every spiral of every order to the periphery of the correspondent circle, viz. if the number of the order be doubled for the periphery of the circle, and the next antecedent odd number be taken for the spiral line; so what we have hitherto demonstrated supplies also another rule, to define the proportion of the spiral space in any order to its circle. For since the circles are in a progression of Squares 1, 4, 9, 16, &c. but the first circle is to the first space as 3 to 1 (i. e. 2, 1 to $\frac{1}{3}$) by Prop. 17. and the second to the second as 12 to 7 (i. e. as 4 to $2\frac{1}{3}$) by Prop. 18. the third to the third as 27 to 19 (i. e. as 9 to $6\frac{1}{3}$) by Schol. 1. of this. And contemplating both these series one by another,

Of the circles, 1, 4, 9.

Of the spaces, $\frac{1}{3}$, $2\frac{1}{3}$, $6\frac{1}{3}$.

We see the numbers of the spaces are produced, if from the square numbers of the circles you subtract their roots, and add to the remainder $\frac{1}{3}$. Wherefore, if, e. g. we were to determine the proportion of the fourth circle to the fourth spiral space; the square of 4 viz. 16 would give the circle; hence subtracting the root 4, there will remain 12, and adding $\frac{1}{3}$ you would have the fourth spiral space $12\frac{1}{3}$; and in like manner the spiral space $20\frac{1}{3}$ would answer to the circle 25, &c. And that this is certain is hence evident, that if we multiply these numbers 16 and $12\frac{1}{3}$, also 25 and $20\frac{1}{3}$ by 3, that we may have those proportions in whole numbers, 48 and 37, 75 and 61, these are those very numbers Archimedes had hinted at in the Coroll. of Prop. 25.

CON-

142

145

144

143

146

217

CONSECTARY X.

NAY what we have now said, is that very *Coroll.* comprehending also that 25th. *Proposition*, viz. that a spiral space of any order is to its correspondent circle, as the rectangle of the semidiameters of this and the preceding circle together with a third part of the square of the difference between both semi-diameters to the square of the greatest semidiameter. For, if e. g. the proportion of the third spiral space to the third circle be required, since the semidiameter of this third circle is as 3, and the semidiameter of the second precedent one is 2, and so the difference 1; the rectangle of 2 into 3 i. e. 6, together with $\frac{1}{3}$ of the square of the difference will define the third spiral space $6\frac{1}{3}$; since the third circle may be defined by the square of the semidiameter of the greater, viz. by 9, and so in the rest; as the numbers we have found shew, or further that may be found according to given Rules which may be here seen in the following Table.

Orders.	I	II	III	IV	V	VI	VII	VIII	XI	X
Circles.	1	4	9	16	25	36	49	64	81	100
The whole spaces, the preced. ones being included.	$\frac{1}{3}$	$2\frac{1}{3}$	$6\frac{1}{3}$	$12\frac{1}{3}$	$20\frac{1}{3}$	$30\frac{1}{3}$	$42\frac{1}{3}$	$56\frac{1}{3}$	$72\frac{1}{3}$	$90\frac{1}{3}$
Separate spaces the preced. ones be- ing excluded.	$\frac{1}{3}$	2	4	6	8	10	12	14	16	18

CONSECTARY XI.

OUT of which table it is obvious to fight, that the second space excluding the first is sextuple of the first, as we have already deduced in *Consect. 2. Prop. 18.* and the third separate space double of the second, and the fourth triple of the same second, and the fifth quadruple, and so onwards.

SCHO-

S C H O L I U M III.

AND this shall suffice for spirals, which comprehends not only the chief Theorems of *Archimedes* of spiral spaces, but also the chief of spiral lines (whereof *Archimedes* has left nothing.) If any should have a mind to carry on our method further, he may easily demonstrate after the same way what remains in *Archimedes*, and what *Dr. Wallis* in his *Arithmetick of Infinites* from *Prop. 5.* to the 38, and what others have done on this Argument.

C H A P. V.

Of the Conchoid, Cissoid, Cycloid, Quadratrix, &c.

Proposition XIX.

THE first conchoid of *Nicomedes* *Bbb* (*Fig. 110*) on both sides of the perpendicular *cDb* approaches nearer always to the directrix or horizontal line *AE*, and yet will never coincide with it, altho' it be conceived to be produced on both sides ad infinitum.

Demonstration.

For since only *Db* is perpendicular to *AE*, and all the rest *ab* are so much the more inclined to it by how much the more remote they are from the middle one *Db*, and all in the mean while are equal both to it and to one another, by *Def. 13.* it is evident that the points *b* and *B* will come so much the nearer to *AE*, by how much the farther they recede from the middle line *Db*. And yet because the lines *BAC* and *bac* are all right ones, whose points *A, a*, are in a right line *AE* it is equally as impossible that the point *b* or *B*, which is always in the conchoid should ever touch this right line, as it is impossible that the point *C* should be in it, by virtue of the aforementioned *Def. Q. E. D.*

Propo.

Proposition XX.

YET no other right line can be drawn between the directrix AE and the conchoid, but what will cut it if produced.

Demonstration.

For if such a right line be made parallel to AE, as GH, and you make, as DI to IC so Db to a fourth, which will be greater than IC, as Db is greater than DI, and consequently, if making that an interval you draw the circular arch from C, it will necessarily cut the line GH *e. g.* in G. Drawing therefore CaG. you'll have as DI to IC so aG to GC, *i. e.* to that fourth proportional before found, by virtue of *Prop. 34. lib. 1.* but as DI to IC, so was also Db to the same fourth by Construction. Therefore aG and Db, which have both the same proportion to the same quantity, are equal; and consequently the point G is in the conchoid by virtue of *Def. 13.* and consequently the right line GH being produced will cut that produced also, on both sides, by the same reason. Much more will it cut it on either side if it be not parallel to the directrix AE, which is very obvious. Therefore no right line can be drawn between the conchoid, &c. Q. E. D.

CONSECTARY.

HENCE, besides other Problems, that may be very easily solved, which requires, having any rectilinear angle given ABC (*Fig 143.*) and a point without it, from that point to draw a right line DEF, so that part of it EF, which is intercepted between the legs of the angle, shall be equal to a given line Z. For if you draw the perpendicular DGH from the given point D through the nearest leg of the angle BC, and make GH equal to the given line Z, and from the center C at the interval GH describe the conchoid IHK, which will be necessarily cut by the other leg of the angle by virtue of the present *Prop. e. g.* in F, the line DF being drawn will
 u give

give the intercepted part \equiv GH by the nature of the conchoid, and consequently \equiv to the given line Z.

S C H O L I U M.

BY means of this Confectary *Nicomedes* solves that noble Problem of finding two mean proportionals, after this way, which we will here shew from *Eutocius*, but drawn into a compendium, and somewhat changed as to the order. Let two given lines AB and BC (*Fig. 144.*) between which you are to find two mean proportionals, be joined together at right angles, and divide both into two parts in D and E, and having compleated the rectangle ABCL, from L thro' D draw LG to BC prolonged; so that after this way GB may become \equiv AL or BC: Having let fall a perpendicular from E cut off from C at the interval CF \equiv AD the part EF, and having drawn FG make CH parallel to it; and lastly thro' the legs of the angle KCH draw the right line FHK, so that the part HK shall be equal to the line CF, by the preceding Confect. and also draw the right line KM from K thro' L to the continued line BA: All which being done, CK and AM will be two mean proportionals between AB and BC; which after our way we thus demonstrate: By reason of the similitude of the \triangle \triangle MAL and LCK

MA is to LC or AB as AL or BC to CK

$b \text{ ————— } eb \text{ ————— } c \text{ ————— } ec$

and moreover,

as MA to AD so GC to CK *i. e.* FH to HK

$b \text{ — } \frac{1}{2}eb \text{ — } 2c \text{ — } ec$ by reason of GF and CH being parallel, by *Confect. 4. Prop. 34. lib. 1.* therefore since HK is \equiv AD $\equiv \frac{1}{2}eb$, FH will be \equiv A $\equiv b$, and consequently MD \equiv FK, *viz.* both $b + \frac{1}{2}eb$, and the square of both $\equiv bb + eb + \frac{1}{4}eebb \equiv \square EF + \square EK$ by vertue of the *Pythag. Theor.* Now if to these equal quantities you add the equal \square DX and EC $\equiv \frac{1}{4}cc$, their sum, *viz.* $\square MD + \square DX$ *i. e.* $\square MX$ will be $bb + ebb + \frac{1}{4}eebb + \frac{1}{4}cc$, equal to the sum of these, *viz.* $\square EF + \square EC$ *i. e.* $\square CF$ (by the *Pythag. Theor.* or EX by Construct.) $+ \square KX$; whence these two things now follow: 1. That the lines MX and KX are equal, 2. If from those equal sums you take away the common quantities

ties $\frac{1}{2}ebb + \frac{1}{2}cc$, the remainders will be equal, viz. $bb + ebb = ecc + eecc$; and (since the part taken away, viz. bb is manifestly to the other part taken away, viz. ecc as the remainder ebb to the remainder $eecc$, and the whole with the parts taken away and the remainders are in the same proportion by Prop. 26. lib. 1.) separately also bb will $= ecc$ and $ebb = eecc$. But from the latter equation it follows that

as eb to ec so ec to b by vertue of the 19. Prop. lib. 1.

AB to CK so CK to MA

and by the same reason it follows from the former Equation

as ec to b so b to c

CK to MA so MA to BC i. e. CK and MA are two mean Proportionals between AB and BC. Q. E. D.

From which deduction you have also manifest the foundation of that mechanical way, which Hiero Alexandrinus makes use of in Eutocius, lib. 2. of the Sphere and Cylinder, and which Swenterus has put into his practical Geometry lib. 1. Tract. 1. Prop. 23. when, viz. having joined in the form of a rectangle the given right lines AB and BC (Fig. 145.) and continued them at the other ends, he so long moves the ruler in L, having a moveable center, backwards and forwards, till XK and XM by help of a pair of compasses are found equal. To which, another way of Philo's is not unlike, and flows from the same fountain, wherein, having made on AC a semicircle, the moveable ruler in L is so long moved backwards and forwards, until LM and NK are found equal: Which seems to Eutocius to be more accommodated to practice, and easier to be perform'd by help of a ruler divided into small equal particles.

Proposition XXI.

IF from any point of the other diameter in the generating circle e. g. from G (Fig. 111. n. 1.) you draw a perpendicular GE thro' the cissoid of Diocles. the lines CG, GE, GD, and GH will be continual proportionals.

U 2

Demon

Demonstration.

For since GE and IF, as right lines, and also GD and IC as versed lines of equal arches by the Hypoth. are equal; you'll have as ID to IF (*i. e.* CG to GE) so IF to IC (*i. e.* GE to GD) *per n. 3. Schol. 2. Prop. 34. lib. 1.* But GD is to GH as ID to IF (*i. e.* as GE to GD) by the forecited *Prop. 34. lib. 1.* Therefore CG to GE, GE to GD, and GD to GH, are all in the same continual proportion. Q. E. D.

CONSECTARY.

Hence it was easie for *Diocles* to find two mean proportionals x and y between two given right lines V and Z; (*Fig. 146*) for he made (having first described his curve DHB) as V to Z so CL to LK, and having drawn CKH to the curve, and thro' H the perpendicular GE, he had between CG and GH two mean proportionals GE and GD by vertue of the present *Prop.* when in the mean while CG the first would be to GH the last, as CL to LK, *i. e.* as the first V to the last Z given by vertue of the Constr. Therefore nothing remain'd but to make, 1. as CG to GE so V to X; and lastly, as GE to GD so x to y .

SCHOLIUM.

IT may not be amiss to mention here another way of finding two mean proportionals between any two given lines by the help of two Parabola's, which *Menechmus* formerly made use of, *viz.* by joining at right angles the given lines AB and BC (*Fig. 147.*) and prolonging them as occasion shall require thro' E and D; and then describing a Parabola about BE as its axis, so made that BC shall be its *Latus Rectum*, and in like manner describing another Parabola about BD as its ax, that shall have AB for its *Latus Rectum*, and that shall cut the former in F: Which being done, the semiordinate FE (or BD which is equal to it) being drawn to the point of Interfection F, will be the two mean proportionals sought. For by vertue of the fourth Consectary of *Prop. 1.* of this Book, DF or BE

BE is a mean proportional between AB and BD, and in like manner EF or BD is a mean proportional between BE and BC, and consequently as AB to BE so BE to BD, and as BE to BD so BD to BC; Q. E. D.

To this way of *Menechmus* that of *Des Cartes* is not unlike, which he gives us *p. m.* 91. except only that instead of two Parabola's, he makes use only of one and a circle in room of the other: In imitation of whom *Renatus Franciscus Slusius* has since shewn infinite methods of doing the same thing by help of a circle, and either infinite Ellipse's or Hyperbola's, in his ingenious Treatise which he thence names his *Mesolabium*.

Proposition XXII.

ANY semiordinate of the Cycloid as BF (Fig. 148.) or bf is equal to its corresponding Sine in the generating circle as BD, bd, together with the arch of that sine AD or Ad.

Demonstration.

For the motion of the point A describing the semi-cycloid AFE, by *Def.* 11. is compounded of the motion of the orb (or wheel) B along the semi-circle ADC, and of the motion of the centre along the right line BC equal to CE, and consequently to the semi circle it self, or motion of the orb, Therefore as the point A moving to E by the motion of the orb (or wheel) moved or was carried from the diameter AC thro' the whole semi circle ADC 'till it came to AC again, and by the motion of the Centre passes thro' the whole space EG or CE, which is equal to the semicircular arch; thus the same A, when come to F, will have describ'd the quadrant AD, by moving from the diameter AC the quantity of the sine BD, and moreover by the motion of its centre (which is equal to the motion of the Orb) moves from AC the space of DF: And so the semiordinate BF will be equal to the arch AD and to its sine BD taken together; and in like manner the semiordinate bf will be equal to the arch Ad and its sine bd, &c. Q. E. D.

CON-

CONSECTARY I.

Hence may be easily assign'd by help of the cycloid a right line equal to the semi-periphery or any given arch AD or Ad; viz. CE double, or taken twice for the whole circumference, and single for the semi-periphery or half circumference, DF for the quadrant Ad, *df* for the arch AD, &c.

CONSECTARY II.

VHerefore the quadrature of the circle may be geometrically obtain'd according to *Consect. 2. of Def. 15. lib. 1.*

CONSECTARY III.

IF you take Be, *be*, double of the sines BD, *bd*, &c. so that all the indivisibles *bd* taken together, may be to all the indivisibles *be* taken together as BD to Be, a curve described thro' the points *e* will be an ellipsis by *Prop. 11.* and the curvilinear space ADCeA will be equal to the semicircle ACDA.

CONSECTARY IV.

AND since DF (*i. e.* De + eF) is equal to the quadrant DA, by virtue of the present Prop. BD + FG will be also equal to the quadrant (because the whole BG or CE is = to a semicircle) and consequently eF and FG will be equal; in like manner since *df* both above and below is equal to the arch dA, below *bd* + *fg* will be = to the remaining Arch dC: and above *bd* + *ef* (*i. e.* *df*) will be equal to the equal arch dA. Therefore *ef* above and *fg* below are equal, and (since the same may be shewn of all the indivisibles of the same sort throughout) the trilinear figure FGE will be equal to the trilinear eFA.

Prop

(Fig

Proposition XXIII.

THE cycloidal space is triple of the generating circle i.e. the semi-cycloidal space $AECA$ is triple of the semi-circle $ADCA$.

Demonstration.

Since the parallelogram $BCEG$ is equal to the whole circle by *Consect.* 2. of *Def.* 15. *lib.* 1. i.e. to the semi-ellipse $AeCA$, by the present construction the Trapezium $CeGE$ will be equal to the quadrant of the ellipse or the semi-circle. But the trilinear space FEG is \equiv to the trilinear space FAe , by the fourth *Consect.* of the preced. therefore also the trilinear space $AeCEA$ is equal to the semi-circle. Therefore the whole cycloidal space is equal to the three semi-circles. Q. E. D.

Or thus.

Since the whole parallelogram AE is equal to two circles and the semi ellipse $AeCA$ to one; the remaining space $AeCEC$ to one circle, and its half $AeGC$ to a semi-circle. But the trilinear space AeF is equal to the trilinear space FGE by *Consect.* 4. of the preced. Therefore the one being substituted in the other's place the trilinear space $AFEC$ will be equal to the semi-circle: Therefore the remainder of the Parallelogram, i.e. the cycloidal space $AFECA$ will be equal to three semi-circles. Q. E. D.

SCHOLIUM.

TO these short Demonstrations, which we confess we owe for the most part to *Hon. Faber*, we will subjoin another somewhat more prolix, but yet not unpleasant, which we find in *Carolus Renaldinus, lib. 1. de Resol. & Compos. Math.* p. 299. But here we will give it the Reader more plain, and free from all Scruples, and likewise much easier. It is perform'd in these inferences, 1. That the right-lined Parallelogram AbB (*Fig.* 149 *n.* 1) is equal to the curvilinear space $AbdaBDA$.
2. That

2. That as that is divided into two equal parts by its right lined diagonal Aa , so likewise is this by the semi-cycloid Aaa , so that the right lined triangle AaB is equal to the curvilinear space $AaaBDA$. 3. Therefore the one as well as the other is equal to the generating circle; and consequently, 4. If to this curvilinear space there be added the semi-circle $ADBA$ the semi-cycloidal space $AaaBA$ will be equal to three semi-circles. The first is evident, while if you take from the right lined parallelogram the semi-circle $ADBA$ on the one side, and on the other add the semi-circle $abda$, there will arise the curvilinear Parallelogram. The third is evident from *Consect. 2. Def. 15. lib. 1.* Because the line Ba is equal to the semi-periphery, which multiplied by the diameter BC gives the area of the circle. The fourth is self evident; and so there remains only the second to be demonstrated, *viz.* That the curvilinear parallelogram is divided into two equal parts by the cycloid, *i. e.* that the external trilinear Figure $AadbA$ is equal to the internal one $AaaBDA$; which may be thus shewn: Having divided the base Ba into three equal parts, and drawn thro' them three semi-circles, and moreover the transverse right lines Dd and Ee thro' the intersections of the semi-circles and the cycloid; it is certain from the genesis of the cycloid, by virtue of the *Conf. of Def. 11.* that as the right line aI is a third part of the whole aB , so the arch $1a$ is a third part of the generating periphery, and by the same reason the arch $2a$ two thirds, and so the remaining arch aII also $\frac{1}{3}$; insomuch that the first arch $1a$, and the last aII , and consequently their right lines af , ag , and likewise their versed ones fI , gI , are equal, and so the curvilinear partial Parallelograms, both above and below, all upon equal bases, and of the same height (*viz.* the two linear ones $ae2I$ and $daII$.) are equal among themselves, and so likewise the two pricked or pointed ones $Dd2B$ and $ae bI$. Wherefore if now the base Ba (*n. 2.*) be conceived to be divided into six equal parts, and having drawn semi-circles, and transverse lines thro' their intersections with the cycloid, the arches

and $Va \left. \begin{matrix} 1a \\ 2a \end{matrix} \right\}$ will be $\frac{1}{6} Va \left. \begin{matrix} 2a \text{ and } 3a \\ 1Va \end{matrix} \right\}$, $\frac{1}{6} Va \left. \begin{matrix} 3a \text{ and } 4a \\ 1Va \end{matrix} \right\}$ of a semi-circle,

and to the versed sines of each, *i. e.* the altitudes of the corresponding parallelograms will be equal, and consequently the parallelograms of the internal and external trilinear space that are alike noted or signed will be equal to each other. Now this inscription of curvilinear parallelograms always respectively equal both in number and magnitude, since it may be continued in both the trilinear figures *ad infinitum*; it will evidently follow, that the trilinear figures themselves, whose infinite inscripts are always equal, will be likewise equal to one another.

Proposition XXIV.

THE base of the quadratrix AE (Fig. 150) and the semidiameter of the generating quadrant AD and the quadrant itself BD are in continual Proportion.

Demonstration.

For the quadrant DB is to the radius DA as the arch IB to the perpendicular He by *Consect. 1. Def. 16* and Ib is to He as Ab to Ae by *Prop. 34. lib. 1.* But the arch IB (if it be conceived to be less and less *ad infinitum*) will at length coincide with Ib, as ending in the same moment in the point B, where in He will end in the point E, and so Ae will end in AE and Ab in AB. Therefore at length DB will be to DA as IB (*i. e.* Ib) to He, *i. e.* as Ab to Ae, *i. e.* as AB (or DA) to AE. Q.E.D.

SCHOLIUM I.

CLavius about the end of the sixth Book of *Euclid*, and others, demonstrate this indirectly by a deduction *ad Absurdum*, or concluding the opposite much after this manner: If DA or AB is not to AE as DB to DA, suppose it to be so to the greater Af or the less Ae. In the first case therefore, because AB is to Af as DB to DA *per Hypoth. i. e.* as Kf to Af the quadrant Kf and the radius AB or DA will be equal. But as BD is to IB so is Kf to Hf by reason of the similitude of the arches; and as BD to IB so also DA (or = Kf) to the line He, by

X

Consect.

Consect. 1. Def. 16. Therefore the sine He and the arch Hf (to which the same Kf bears the same proportion) will be equal; which is absurd. In the latter case, because AB would be to Ae as LB to DA by the hypoth. *i. e.* as Le to Ae , the quadrant Le and the radius AB or DA would be again equal. But as BD is to IB so is Le to Me by reason of the similitude of the arches; and as BD to IB so also is DA (*i. e.* Le) to He by *Consect. 1. Def. 16.* Therefore the tangent He and the arch Me (to which the same Le bears the same proportion) will be equal, which is again absurd. Wherefore BD is to DA , not as DA to a greater Af or a less Ae ; therefore as DA to AE . Q. E. D.

CONSECTARY I.

Wherefore it is evident from what we have deduced, if by means of the base of the quadratrix AE you draw a quadrant, the side of the quadratrix DA will be equal to it, and consequently double of the semi periphery, and quadruple of the whole periphery.

CONSECTARY II.

IT is evident also that you may obtain a right line equal to the quadrant DB of any given circle, if, having described a quadratrix, you make as AE to AD so AD to a third equal to the quadrant DB : Which third proportional taken four times will be equal to the whole periphery.

CONSECTARY III.

YOU may also obtain a right line equal to any less arch, if you make, as DA to He so a third proportional found (*i. e.* the quadrant DB) to a fourth, by virtue of *Conf. 1. Def. 16.*

CONSECTARY IV.

THE quadrature of the circle therefore, by vertue of *Conf.* 1. *Def.* 15. *lib.* 1. as likewise the trisection of an angle, by vertue of *Confect.* 2. *Def.* 16. *lib.* 2. may be Geometrical-ly obtain'd, if the Quadratrix might be number'd among Geometrical Curves.

S H C O L I U M II.

Clavius was also of this Opinion in the book afore mentioned, who thought that if the quadratrix be excluded out of the number of geometrical curves, by the same reason you may also exclude the ellipse, parabola, and hyperbola, since they as well as this are commonly described thro' innumerable points. But by that great Man's leave, we may deny this consequence, by the same reason as *Des Cartes* has deny'd the converse of it in his *Geom.* p 18. and 19. by vertue of which he suspects the ancients took the conick sections, &c. for mechanick or non-geometrick lines, because they did the spiral, quadratrix, &c. for such. But this is the difference between the description of the quadratrix and the conick sections thro' points, that all and every of the points of the conick sections, relating to any given point of the axis, may be geometrically determin'd; but all the points of the quadratrix promiscuously related to any point of the generating quadrant, cannot be geometrically determin'd, but only those which respect some certain point, from which the quadrant may be divided into two arches of known proportion. For if, e g. in the quadrant BD the point X be given at pleasure, it will be impossible by *Clavius's* Rule to define a point of the quadratrix answering to it, because the proportion of the arches DX and BX is unknown, and consequently neither can a proportional section of the right line AD be made: Not to mention that the last point E (which is the primary and most necessary one to the quadrature) even by *Clavius's* own confession cannot be geometrically defined. We may pass the like judgment on *Archimedes's* spiral and such like curves, which are conceiv'd to be described by two motions independent on one another; as

will be manifest to any one who compares the genesis of the spiral with that of the quadratrix and what we have hitherto said. Whence neither will *Monantholus's* trisection of a given angle (which he essays) by means of a spiral be enough geometrical; which in his Book *de Puncto*, Cap. 7. p. 24. he attempts to perform thus: To the centre of a described spiral and its first helical or spiral line BA (*Fig. 151.*) he applies the angle ABC equal to the given one *abc*; then having drawn circles thro' F and A where the legs of the angle cut the spiral, he divides the intermediate space DA into three equal parts in I, and K: And then thro' these points he draws circles cutting the helix in L and M; and lastly having drawn BLN, BMO, he easily demonstrates from the genesis of the spiral that the arches AO, ON, NC are equal. And so after the same manner not only any angle or arch, but the whole periphery may be geometrically divided into as many parts as you please; only supposing that this spiral line may be numbered among geometrical ones; as we have heretofore hinted that the cycloid, conchoid, cissoid, and logarithmical curve, &c. might be; and we have above sixteen Years ago declared our opinion for it in our German Edition of *Archimedes*; and now are therein confirm'd by those celebrated Mathematicians *Leibnitz*, *Craige*, &c. who number lines of this kind, altho' they cannot be expressed by our common equations, among geometrical ones, notwithstanding the contrary opinion of *Des Cartes*, &c. because they admit of equations of an indefinite or transcendent degree, and are capable of a *Calculus* as well as others, tho' it be of a nature and kind different from that commonly used. See the *Acta Erud. Lips. ann.* 84. p. 234 and *ann.* 86. p. 292. and 294.

C H A P. VI.

The Conclusion, or Epilogue of the whole Work.

NOW we may at length understand what *Honoratus Fabri* delivers concerning the distribution of figurate magnitudes into certain Classes, in his *Synopsis Geom.* p. 57. and the following.

1. The first Classe contains elementary figures, or equal indivisibles, such as, 1. All Parallelograms, as the Square, Oblong, Rhombus and Rhomboid, the elements whereof are equal right lines, as in *Def. 12. lib. 1.* 2. Convex or concave Surfaces, the elements whereof are curve lines moved thro' right lines by a parallel motion; among which are chiefly reckon'd cylindrical surfaces, whereof see *Def. 16. lib. 1.* about the end. 3. Parallelepipeds, and among them the cube, whose indivisibles are squares, or other Parallelograms.

4. Prisms made by the motion of a Triangle, Trapezium, or any Polygonous Body, along a right line, all the indivisibles whereof are consequently similar and equal to the generating plane.

2. The second Classe contains Figures whose Elements decrease in a simple arithmetical Progression; such are, 1. Triangles, as is evident from *Prop. 37. lib. 1.* 2. The circle, and its Sectors, as resolvable into concentrick Peripheries according to *Conf. 1.* and 3. of the aforecited *Prop.* 3. The Cylinder as resolvable into concentrick cylindrick Surfaces, as its indivisibles. 4. The Surface of a Cone, whose elements are circular Peripheries, and also of the Pyramid whose indivisibles are similar angular Peripheries every where increasing in arithmetical Progression. 5. The *Parabolick Conoid*, whose indivisibles are Circles according to the proportion of the abscissa's in arithmetical Progression, by vertue of *Prop. 14. lib. 2. &c.*

3. The third Classe contains elementary Figures increasing in duplicate arithmetical Progression; such are, 1. The Pyramid and Cone, the first whereof may be resolv'd into angular Planes, the second into circular ones increasing according to a series of square numbers; as is evident from *Prop. 38. lib.*

lib. 1. and its Confectary. 2. The trilinear parabolick Space, as defin'd *Prop.* 10. *lib.* 2. by the letters *Eb EIK*. 3. The Sphere, as far as it may be resolv'd into spherical concentrick Surfaces, every one whereof may be consider'd as a base, taking the semidiameter for the altitude. 4. The Cone, as resolvible into parallel conical Surfaces describ'd by the parallel indivisibles of the Triangle. 5. The remainder of a Cylinder after an Hemisphere of the same base and altitude is taken out, according to *Schol.* 1. of *Prop.* 39. *lib.* 1.

4. The fourth Classe would comprehend all magnitudes resolvible into elements or indivisibles increasing in triplicate, quadruplicate, &c. Arithmetical Progression; such we have not treated of, but may be found among Planes terminated by Curves of superior Genders; see *Fabri's* Synopsis, p. m. 67.

5. The fifth Classe is of those Magnitudes, whose indivisibles decrease, proceeding from a square number by odd numbers, as, 36, 35, 32, 27, 20, 11, &c. such are, first, an Hemisphere, as is evident from *Prop.* 39. *lib.* 1. 2. An Hemispheroid, as in *Prop.* 15 *lib.* 2. 3. A Semi-parabola, as may be gather'd from the demonstration of *Prop.* 10 *lib.* 2. For since the indivisibles of the circumscrib'd trilinear figure *eb* are found in a duplicate arithmetical Progression, $\frac{1}{4}, \frac{4}{4}, \frac{9}{4}, \frac{16}{4}$, the indivisibles of the semi-parabola will necessarily be $\frac{16}{49}, \frac{15}{49}, \frac{12}{49}, \frac{7}{49}$ &c.

6. We may make a sixth Classe of those Magnitudes whose indivisibles decrease in a like Progression, not of the numbers themselves descending by odd steps from a given square, but of their roots, which are for the most part surd ones, such as is first, the Semi-circle, as is evident from *Prop.* 43. *lib.* 1. and by vertue of *Prop.* 5. *lib.* 2. and also the semi-elliptic, &c.

7. The seventh Classe comprehends those Magnitudes, whose Elements are in a Progression of a double series of numbers, as in the Parabolick Conoid, as may be seen in the *Scholium* of *Prop.* 16. *lib.* 2.

But, to omit the other Classes of Magnitudes of a superiour Gender, the consideration whereof these Elements either have not touch'd on, or only by the by; (which any one who pleases may see in *Faber's* Synopsis, especially those which he comprehends under the sixth and seventh Classes, p. 70 and the following) about those we have here particularly noted, there remain

main only two things to be taken notice of. 1. That since in the first Classe we place Parallelograms and Cylinders, in the second Triangles, in the third Pyramids and Cones, in the fifth Hemispheres, in the sixth semi-circles, &c. We may with *Hon. Faber* call the first Classe, that of Cylindrical or Parallelogrammatick Figures; the second, the Classe of Triangular Figures; the third, of Pyramidals; the fifth, of Hemispherical Figures; the sixth of semicircular ones, &c.

2. That having ranged or reduced after this manner homogeneous Figures, or those of like condition, to a few Classes, their dimension, and consequently almost the whole business of measuring may be very compendiously reduc'd to a few Rules; whereof we will here give the Reader a short Specimen, in the following

CONSECTARYS.

I. THE dimension of Parallelogrammatick Figures, *i. e.* of those of the first Classe, may be had, by multiplying the whole base by the whole altitude: See *lib. 1. Def. 12. Conf. 7. Def. 18. Conf. 6. Def. 16. Conf. 3.* and 4.

II. The dimension of Triangular Figures, *i. e.* of those of the second Classe, may be had by the multiplication of the whole Base by half the Altitude, or of half the Base by the whole altitude; [see *lib. 1. Def. 12. Consect. 8. Def. 15. Consect. 2. Def. 18. Consect. 4. lib. 2. Prop. 14*] and their Proportion is to their respective circumscribing Parallelograms, as 1 to 2; [see besides the *Prop.* already cited, *lib. 1. Prop. 37.* and its first *Consect.*]

III. The dimension of Pyramidals, *i. e.* of magnitudes of the third Classis, may be obtain'd by the multiplication of the Base by the third part of the of Altitude; [see *lib. 1. Def. 17. Consect. 3. and 4. and Def. 20. Consect. 1. &c.*] and their Proportion to the corresponding Figures of the Classe of the same Base and Altitude is as 1 to 3. [see besides the *Prop.* already cited *Prop. 38. lib. 1. and its Conf. Prop. 39. and Schol. 1. lib. 2. Prop. 10. &c.*

IV. The

IV. The Proportion of Hemispherical Magnitudes, *i. e.* of the fifth Classis to corresponding ones of the first Classe of the same Base and Altitude is as 2 to 3; [see *lib. 1. Prop. 39. lib. 2. Prop. 10. and 15.*] and so their dimension may be had by multiplying their Base by $\frac{2}{3}$ of their Altitude.

V. The Proportion of semi-circular Magnitudes, *i. e.* of those of the sixth Classe to so many corresponding ones of the first Classe of the same Base and Altitude cannot be expressed by whole numbers or by a small fraction [see *lib. 1. Prop. 43. and lib. 2. Prop. 11.*] and consequently their exact numeral dimension cannot be had.

SINCE those ingenious Mathematicians of this present Age, which is now drawing to a Conclusion, Vieta, Oughtred, Harriot, Cartes, Schooten, Beaune, Van Hudde, Heuraet, de Witte, and Slufius, and several other Famous Men coeval with them, have by their Endeavours improved the Algebra of the Ancients, raised it to vastly an higher pitch, and brought it from Numbers to universal Symbols, and not only found the excellent uses of it in Geometry themselves, but also communicated them to others; almost all Countries have furnished us with some excellent Persons, who treading in the footsteps of their Predecessors, have endeavoured to advance it yet further: And even our Times are not without those of the highest rank, as Wallis, Baker, Renaldinus, Mengolius, Huggins, Malbranch, Leibnitz, Craan, and several others, who endeavour to promote this Science, deservedly reputed the very Apex of Humane Reason, and carry it more and more towards its utmost Perfection by daily augmenting it with new and curious Inventions. But in the mean time, while these ingenious Men wholly busie themselves in promoting it, there are few found who condescend to explain the first Principles of it, and shew a ready way to young Beginners to arrive at the knowledge of those Inventions. It is not long since a certain Friend of mine, who for some time has publickly and successfully taught these Sciences,

complain'd

A a 2

The Preface to the Reader.

complain'd to me by his Letters, of the want of a good Guide to Specious Analysis, whereby he might instill the Principles of that admirable Art into his Auditors. To whose Desires being not just then at leisure to satisfy, I immediately after projected this Introduction, which at length you see finished, in the Form we now present you with it, wherein we have all along consulted to suit the Endeavours of young Beginners, as far as possible; as we thought our selves engaged by the Duties of our Professorship to do, & have compriz'd the Precepts of the Art in six or seven Pages, and accommodated Examples of every kind to illustrate them. Wherein if I have but indifferently accomplish'd my Design I shall not think my Labour lost. We here add it to our Mathesis Enucleata, both as being properly a part of it, and more especially, because this Introduction presupposes the Reader to be acquainted with the first Principles of Specious Computation, which we have therein laid down. And so we commit our Endeavours to the Perusal and Censure of the Candid Reader.

INTRO.

INTRODUCTION

TO

SPECIOUS ANALYSIS.

THE *Analytick Art*, or *Specious Analysis*, is solely subvervient to finding of Theorems, and resolving Problems, by leading us from certain *Data* or given Quantities, into the knowledge of unknown and sought ones, by a Chain of certain and infallible Consequences: This admirable Artifice may be reduced to four Primary Heads, *viz.* *Denomination*, *Reduction*, *Equation*, and *Effection* (if the Problem be a Geometrical one) or *Construction*.

I. DENOMINATION.

BY Denomination is understood a preparatory imposition of Names peculiar to each Quantity, whereby every one of the Quantities given or sought, are denoted by one or more peculiar Letters of the Alphabet at pleasure, but with this (arbitrary) difference, that known or given quantities are mark'd by the former Letters of the Alphabet, *a, b, c, &c.* and the unknown or sought ones by the latter; *z, y, x, &c.* But although this imposition of Names, is, as we have said, altogether arbitrary, yet there often happens not a little facility to the Solution it self, by its being chosen as accommodate as possible to the conditions of the quantities given and sought; which any one will learn better by Use than Precepts: As we find that both Theorems may be demonstrated, and Problems resolved *e. g.* by an extraordinary Compendium, if we denote any reason of two given Homogeneous quantities by *a* and *e a*, *b* and *i b*, *d* and *o d*, &c. (*v. z.* by expressing the Names of the Reasons by *e*, and *i*, and *o*, &c.) and continued proportionality

onality by $a, ea, e^2a, e^3a, \&c.$ and discontinued or discrete by bib, cic, did , or after the like manner, as we have done in our *Math. Enucl. Lib. 1. Cap. 2, 3, 4, 7.* and *Lib. 2. Cap. 1. &c.*

II. EQUATION.

HAVING thus given each quantity its Name, and making no further distinction between the quantities given and those sought, but treating them all promiscuously, and as already known, you must carefully search into and discuss all the Circumstances of the Question, and making various Comparisons of the quantities, by adding, subtracting, multiplying, and dividing them, *&c.* till at length, which is the chief aim and design of it, you can express one and the same quantity two ways; which is that we call an *Equation*: And you must find as many of these Equations, or Equalities of literal quantities, (as expressing the same thing) as there are several unknown quantities in the Question, independent on each other, and consequently denominated by so many different Letters, $z, y, x, \&c.$ But if so many Equations cannot be found, after having exhausted all the Circumstances of the Questions by one or two Equations; that is a sign the other unknown quantities may be assumed at pleasure: Which the Examples we shall hereafter bring will more fully shew.

But as here also (as likewise in all this Art) Ingenuity and Use do more than Rules and Precepts; yet we will here shew the principal Fountains, for the sake of young Beginners, whence Equations, according to circumstances obvious in the Question, are usually had. These are partly Axioms self evident, *E. g.*

That the whole is equal to all its parts taken together.

That those quantities which are equal to one third, are equal among themselves.

That the Products or Rectangles under the Parts or Segments, are equal to the Product of the whole.

Partly some universal Theorems that are certain and already demonstrated, as,

Three

(a)
(b)
(c)
(d)

Three (α) continual Proportionals being proposed, the Rectangle of the Extremes is equal to the Square of the mean.

(β) Four being proposed, whether in continued or discontinued Proportion, the Product or Rectangle of the Extremes is equal to that of the Means.

And several others such like, which we have demonstrated in Cap. 2, 3, and 4. Lib. 1. of our *Mathesis Enucleat.* partly in the last place, some particular Geometrical Theorems already demonstrated, as e. g. that common Pythagorick one.

That in rightangled Triangles (γ) the Square of the Hypotenuse is equal to the two Squares of the sides.

That the Square of the Tangent of a (δ) Circle is equal to the Rectangle of the Secant and that Segment of it that falls without the Circle; the first whereof, we have demonstrated, Lib. 1. *Math. Enuc.* Def. 13. Schol. and also Prop. 34. Consect. 8. also Prop. 44. after various ways; to which may be numbred Prop. 34. with Schol. 11. n. 3. Prop. 37. and following, Prop. 45. and 46. also the 48. and several others in Lib. 1. *Math. Enuc.* and likewise Lib. 2. Prop. 1, 2, 3, and several following. And as for Examples both of Denomination, and Equations found after various ways, you may see them hereafter follow, and some we will here give you by way of Anticipation.

III. REDUCTION.

An Equation thus found must be reduc'd, i. e. those two equal quantities, which for the most part are very much compounded of the quantities given and sought together, must be reduc'd to such a form, by adding or subtracting something to or from each part, or multiplying and dividing by the same, &c. that the unknown or sought quantity alone, or its Square or Cube or Biquadrate, &c. may be found on the one side, and on the other the quantity express'd by meer given or known Letters, or affected with the unknown and sought ones; such are these Forms which follow, distinguish'd by their Names prefix'd to them,

(α) *Eucl.* 6. 17.

(β) *id.* 6. 16.

(γ) *id.* 1. 47.

(δ) *id.* 3. 36.

A simple Equation, $z = b$, or $y = \frac{a b}{c}$.

A pure Quadratick, $y y = a b$, or $x x = \frac{a a - b b}{2}$.

A pure Cubick, $z^3 = a b c$, or $y^3 = \frac{a^3 b b}{c d}$.

An affected Quadratick, $x^2 = -a x + b^2$; or,
 $y^2 = 2 b y + \frac{2 a b c}{d}$.

An affected Cubick, $z^3 = a x^2 + b^2 x - c^3$ &c.

A Biquadratick, $y^4 = a y^3 + b^2 y^2 - c^3 y + d^4$ &c.

To one of which, or some other like them, when you have reduc'd your Equation first found, there are Rules in reading whereby the Value of the unknown or sought quantity z , or x , may be either exprest in Numbers, if the Question be an Arithmetical one, or geometrically determin'd if it be a Geometrical one: Which is that we call *Effectiō* or *Constructiō*.

Thus therefore the whole, or at least the chief business of Analyticks, is conversant in finding a convenient or fit Equation: For Reduction is very easie, and consisting only in certain Operations and mere Axioms, as *e. g.*

If to equal quantities you add or subtract equal ones, the Aggregates or Remainders will be equal;

If equal quantities are multiplyed or divided by the same, the Products or Quotients thence arising will be equal, &c.

EFFECTION, or CONSTRUCTION.

1. In simple Equations.

Suppose $z = b$, the quantity b is sought.

If z be $\frac{ab}{c} \dots$ { as c to b so a to z ,
 or $x = \frac{aa}{b} \dots$ { as b to a so a to x ,
 or $y = \frac{fb + fg}{b - 1}$ make { as $b - 1$ to $b + g$ so f to y ,
 or $z = \frac{fb - fg}{b + 1}$ { as $b + 1$ to $b - g$ so f to z , &c.
 every where according to *n. 2.*

Schol. 2. Prop. 34. Lib. 1. *Math. Enuc.*

If z be $\frac{kl + mn}{r + s}$, the Resolution of it into Proportionals

be more difficult, because neither of the Letters are found in the Numerator. That therefore you may have *e. g.* twice, you must make as k to n so m to a fourth Proportion which call p ; then will, by virtue of *Prop. 18. Lib. 1.* $= mn$, and the proposed Equation be changed into this $= \frac{kl + kp}{r + s}$, to be now constructed from the 2d. Case.

Or if $y = \frac{kl + mn}{r - s}$, find a mean Proportional between k

h , which call p ; and between m and n , which call q , according to *n. 3.* of the afore-cited Schol.; and the proposed Equation, by virtue of *Prop. 17.* will be in this form: $\frac{pp + qq}{r - s}$. Make therefore in the right-angled Δ (*Fig. 1.*)

$BC = p$ and $BC = q$; and the $\square AC$ by virtue of the Pythagorick Theorem, $= pp + qq$: Which since it must be divided by $r - s$, make further, by *Prop. 18* as $r - s$ to the $pp + qq$, so is $\sqrt{pp + qq}$ to y , according to the afore-

4 In like manner if x be $\frac{bg - mn}{c + d}$, make 1st. as b to m so n to a fourth which call k ; and so putting bk for mn , the Equation will be reduced to the second Case under this form: $x = \frac{bg - bk}{c + d}$.

Or thus: Find a mean Proportional between b and g , which call p , and between m and n , which call q ; and the proposed Equation will be in this Form: $x = \frac{pp - qq}{c + d}$.

Make therefore (in Fig. 2.) $AB = p$, and having on this described a Semi-circle, apply $BC = q$; then will, by virtue of *Schol. 5. Prop. 34.* $\square AC = pp - qq$: Which since it must be divided by $c + d$, make farther,

as $c + d$ to $\sqrt{pp - qq}$, so $\sqrt{pp - qq}$ to x ; all from the same Foundations, whence you have the Construction of the third Case.

5. If z be $\frac{aabc}{ffg}$; make first as f to a , so a to a third

Proportional m , and you'll have (putting fm for aa) $z = \frac{fmbc}{ffg}$, i. e. $\frac{mbc}{fg}$. Make secondly as f to m , so b to a fourth n , and by putting fn for mb you'll have $z = \frac{fnc}{fg}$, i. e. $\frac{nc}{g}$.

wherefore thirdly you'll have as g to n so c to z .

6. If y be $\frac{bll}{mm}$, make first as m to n , so l to a fourth,

which call n , and by putting now mn for bl , you'll have $\frac{mnl}{mm}$ i. e. $\frac{nl}{m} = y$. Therefore you'll now have secondly, as m to n ,

so l to y by Case 2: So that the Construction of the fifth and sixth Cases is nothing but reiterations of the Rule of three, according to what we have often inculcated, *N. 2. and 3. Schol. 2. Prop. 34.*

2. In simple Quadratick Equations.

1.

$$\left. \begin{array}{l} \text{If } xx = ab \\ \text{or } y^2 = 1c \\ \text{or } z^2 = \frac{3}{4}dd \end{array} \right\} \text{you'll have } \left\{ \begin{array}{l} x = \sqrt{ab} \\ y = \sqrt{1c} \\ z = \sqrt{\frac{3}{4}dd} \end{array} \right. \text{that is to a } \left\{ \begin{array}{l} a \text{ and } b \\ 1 \text{ and } c \\ \frac{3}{4}d \text{ and } d \end{array} \right. \text{mean proportional between}$$

and so the Construction will be had from *n. 3. Schol. 2. Prop. 34.* (see Fig. 3.)

2. If $y^2 = fg + kl$ } you'll have $y = \sqrt{fg + kl}$ make there-
 or $x^2 = fg - kl$ } have $x = \sqrt{fg - kl}$ fore
 on the one side the Right-angled Triangle ABC (Fig. 4)
 whose side

AB is = to a mean Proportional between f and g ;

BC is = to a mean Proportional between k and l ;

On the other a Right-angled Δ (Fig. 5) whose side AB is = to a mean Proportional between f and g , and the side BC = to a mean Proportional between k and l ;

and on the one hand } AC will } y
 the Hypotenusa, } be the va- }
 on the other the side } lue of } x

And all by vertue of the Pythag. Theor. and according to *Schol. 5. Prop. 34.* or the Confectarys of *Prop. 44.* See Fig. 4. and 5.

3. If $z^2 = \frac{fbbkk}{fcc}$ i. e. $\frac{bkkk}{cc}$; extracting the Roots on both sides, z will = $\frac{bk}{c}$, and so be the second case of simple Equations.

4. If y^2 be = $\frac{fgbkk}{lm}$, make first as l to f , so g to a fourth which call n , and by putting ln for fg , you'll have $y^2 = \frac{lnbkk}{lm}$ i. e. $\frac{nbk}{m}$. Make Secondly, as m to n , so b to a fourth, which call p ; and by putting mp for nb , you'll have $y^2 = \frac{mpk}{bb}$

mpk i. e. pk , and so the first case of the present Equations;

m

$$5. \text{ If } x^2 = \underbrace{qbcc + bccd + qbcd + bcdd}_{fg + lm}$$

in the first place the Rectangles fg and lm being turned into Squares, and collected into one Sum, make them $= nn$. Then (since cc and cd are multiplied by $qb + bd$) in like manner qb and bd added make pp ; and you'll have $x^2 = \underbrace{ppcc + ppcd}_{nn}$. Thirdly (since pp is already multiplied by

$cc + cd$) having added $cc + cd$ into one Sum that they may e. g. make rr ; x^2 will $= \underbrace{pprr}_{nn}$, and so be the third case of

the present Equations.

3. In affected quadratick Equations.

IF zz be $= az + bb$, then will $z = \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$; which may be thus in short demonstrated *a priori*: Since $z^2 - az = bb$ per *Hypoth.* and that first quantity if it be added to $\frac{1}{4}aa$, it becomes an exact Square, the root whereof is $z - \frac{1}{2}a$; therefore $z^2 - az + \frac{1}{4}aa = bb + \frac{1}{4}aa$, and consequently $z - \frac{1}{2}a = \sqrt{bb + \frac{1}{4}aa}$; and lastly $z = \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$ or $\frac{1}{2}a - \sqrt{\frac{1}{4}aa + bb}$; which last Root is a false one and less than nothing, but yet gives you the proposed Equation back again as well as the former; as will be evident to any one who tries, viz. having transferr'd $\frac{1}{2}a$ on the other side, and so the two equal quantities $z - \frac{1}{2}a$ and $-\sqrt{\frac{1}{4}aa + bb}$ being squared. For here will come out $\frac{1}{4}aa + bb$ as well as if the radical Sign were affected with the Sign $+$ because $-$ by $-$ gives $+$. Therefore $zz - az + \frac{1}{4}aa = \frac{1}{4}aa + bb$, and taking away on both sides $\frac{1}{4}aa$, $zz - az = bb$ i. e. $zz = az + bb$.

The value therefore of this Root will be had geometrically, by making (in *Fig. 6.*) $CD = \frac{1}{2}a$ and $DE = b$, that the Hypothenusa CE may be $\sqrt{\frac{1}{4}aa + bb}$; and moreover, drawing out on both sides CD , and at the interval CE describing a Semi-circle

mi-circle AEB: This being done, AD will be the value sought of the true Root x , and DB of the false one.

2. If y^2 be $= -ay + bb$, then will $y = -\frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}$; which again may thus appear: Since $y^2 + ay$ is $= bb$ per Hypoth. adding to both sides $\frac{1}{4}aa$, the first quantity will be an exact Square, and $y^2 + ay + \frac{1}{4}aa = \frac{1}{4}aa + bb$. Therefore the Roots will be also equal, viz. $y + \frac{1}{2}a = \sqrt{\frac{1}{4}aa + bb}$, and consequently $y = \sqrt{\frac{1}{4}aa + bb} - \frac{1}{2}a$ or $-\sqrt{\frac{1}{4}aa + bb} - \frac{1}{2}a$; which is a false Root.

The value of these Roots may be had geometrically, viz. of the true Root DB in Fig. 6. or BE in Fig. 7. and of the false one in the first AD, in the second AE.

3. If xx is $= ax - bb$, you'll have

$$x = \frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$$

$$\text{or } \frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}.$$

Which may be demonstrated after the same way *a priori*, as the former Cases, viz. Since $x^2 - ax$ is $= -bb$, adding on both sides $\frac{1}{4}aa$, the former quantity will be an exact Square, viz. $x^2 - ax + \frac{1}{4}aa = \frac{1}{4}aa - bb$. Therefore the Root of the one $x - \frac{1}{2}a =$ to the Root of the other, viz. $\sqrt{\frac{1}{4}aa - bb}$, and adding on both sides $\frac{1}{2}a$, $x = \frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$ which is one of the true Roots. Or $\frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}$ which in this case is also a true one. But the value of each may be obtain'd by making (Fig. 8.) CB $= \frac{1}{2}a$ and by erecting BD perpendicularly $= b$, and making the Semi-circle BEA, and drawing DE parallel to CB, and letting fall the Perpendicular EF: For thus CF will be $\sqrt{\frac{1}{4}aa - bb}$ and consequently AF, $\frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$, and FB $\frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}$.

Or, with Cartes, making (Fig. 9) CB $= \frac{1}{2}a$ and BD $= b$, drawing DF parallel to CB, that FD may be one root and ED the other; as is manifest from the precedent Construction, and its Rule. See also another Deduction from Cartes's Constructions, *Schol. 1 Prop. 47. Lib. 1. Math. Erucl.*

NB. 1. The ingenious Schooten has before shew'd this Method of demonstrating, and also of finding out these Rules in his Comment on the Geometry of Des Cartes, p. m. 163. and moreover deduces another ingenious Method for all the three Cases of these Equations, by taking away the second term in the

the Equation, p. 290, and the following, where we may make only this Remark concerning the third Case; that perhaps the Rule might be better deduc'd, if we make $x = \frac{1}{2}a - z$ rather than $x = z - \frac{1}{2}a$.

NB. 2. If any one has a mind to see the new Constructions of affected quadratic Equations of the Abbot Catelan, he may find them in *Acta Erud. Lips. Ann.* 1682. p. 86. and in the 27th Journal des Sçavans. 1 Dec. 1681.

IV. For Cubick and Biquadratick Equations both simple and affected, and also for all before mentioned, and consequently universally for all not exceeding the fourth Dimension.

THE value of the unknown Quantity or Root may for any Case be determined by one general Rule, found out by Mr. Thomas Baker an English-man, occasioned by what *Des Cartes* had taught concerning this matter, *Lib. 3. Geom.* p. 85, and the following; but now very much perfected by this Rule, and made more simple. Now that this Rule may be the better comprehended by Learners, we will premise these following things.

1. That all Equations occurring under those Forms which we have before shewn in the Article of Reduction, or the like, must always for this purpose be so changed as to have all the terms or parts of the Equation both known and unknown, affected and not affected, brought over to one side promiscuously, and so on the other there will stand 0 or nought, as e.g.

let $z - b$ be $= 0$, or $y - \frac{ab}{c} = 0$, or $z^3 abc = 0$, or

$$y^3 - \frac{a^3bb}{ca} = 0, \text{ or } x^2 + ax - b^2 = 0; \text{ or}$$

$$y^2 - 2by - \frac{2abc}{d} = 0; \text{ or}$$

$$z^3 - az^2 - b^2z + c^3 = 0; \text{ or}$$

$$y^4 - ay^3 - b^2y^2 + c^3y - d^4 = 0 \text{ \&c.}$$

which also was usual to *Des Cartes* in *Lib. 3.*

2. In all Equations the known quantity or Co-efficient of the second Term we will generally denote by the Letter p , that of the third Term by the Letter q , of the fourth by r , and the fifth (or absolute Number) by S ; according to *Cartes*, but with some little alteration: So that hence the Equations we have before been treating of, and all others like them (every where denoting the unknown quantity by x) may all be reduced to these forms:

$$x - p = 0$$

$$x^2 + px - q = 0$$

$$x^3 - px^2 - qx + r = 0$$

$$x^4 - px^3 + qx^2 - rx + S = 0, \text{ \&c. \&c.}$$

3. These and the like Equations may either occur whole, or with all their Terms, as here, or depriv'd of one or more of them, as the following Examples will shew, where we will always put an Asterisk in the place of the deficient Term.

$$x^2 * - q = 0$$

$$x^3 ** + r = 0$$

$$x^4 *** - S = 0$$

$$x^3 * + qx + r = 0$$

$$x^4 * + qx^2 + rx + S = 0$$

$$x^4 + px^3 + qx^2 * + S = 0$$

$$x^4 * * + rx + S = 0$$

$$x^4 + px^3 * * + S = 0$$

4. The unknown quantity in any Equation has † as many diverse Roots or Values, as the Equation has Dimensions; which *Des Cartes* shews, *Lib. 3. Geom. p. 69.* at the same time evidently demonstrating this, *viz.* that some of those Roots may be false ones, *i. e.* less than nothing: Which from him we here suppose.

When therefore *Des Cartes* in his Construction of Cubick and biquadratick Equations, *p. 85,* and the following, requires as a necessary Condition, the ejection of the second Term in the given Equation, unless it were already wanting, and so was obliged to shew a way to eject it, with several other Preparations; and afterwards, when by help of his Rule delivered *p. 91.* he had found a way of finding two mean Proportionals, and dividing

† N. This is an error, as has been prov'd by *Dr. Wallis.*

dividing any given Angle into three equal parts, then he uses it for solving other solid Problems, or finding two mean Proportionals, or trisecting an Angle. But the general Rule of *Baker* has no need of these methods or helps, neither of the Ejection of the second Term, nor any other Preparation, but immediately shews us a way, by the help of a Circle and Parabola to find all the Roots of any given Equation, both true and false, whether the Equation want any term or not, and howsoever affected, after the way we will now, and perhaps a little more distinctly, shew.

1. It supposes with *Cartes* a Parabola *NAM* to be already described, (See *Fig.* 10. and 11.) whose *Latus Rectum* shall be *L* or 1, and its *Axe* *ay*; which *Des Cartes* only making use of, and never thinking of the other Diameters, was forced to take away the second Term of the Equation, &c. *Baker* therefore (strangely perfecting the *Cartesian* Geometry by this one thought) if the quantity *p* or second Term be in the Equation applies to the *Ax ay* (or draws an ordinate to it) $BA = \frac{p}{2}$ i.e. he erects at top of the *Ax a* on the right hand the

perpendicular $aE = \frac{p}{2}$ and from *E* draws *E Ay* parallel to the

Ax ay; whereby he obtains the Diameter *Ay* sought.

2. Having made this Preparation, the whole business depends on this, to find the Center of the Circle to be described through the Parabola, which (by vertue of some arbitrary suppositions in the beginning) he always seeks on the left side of the *Ax* or Diameter, by help of two Lines $\frac{AD}{aD}$ or $\frac{AD}{d}$, and

DH or *d*; viz. by placing the former upon the *Ax* from *a* to *D*, if *p* be wanting in the Equation, or upon the Diameter *Ay* from *A* to *D* if *p* be there; and letting fall from the point *D* the latter to aD or *AD* perpendicularly towards the left hand.

3. He shews how to find the quantity of either of these Lines (which is here very requisite) in any given Equation, by a certain general Rule (which he calls the Central Rule, because it alone helps to find the Center *H*) comprehended in these terms:

Directions for the Bookbinder.

N B. The Sign ∞ denotes a dubious Case, viz. That either the Antecedent must be Subtracted from the Consequent, or the Consequent from the Antecedent, according as the matter will bear.

$$\left\{ \begin{array}{l} 1. \frac{L}{2} + \frac{p^2}{8L} \pm \frac{q}{2L} = b = AD \text{ or } aD \\ 2. \frac{p}{4} + \frac{p^3}{16L^2} \pm \frac{pq}{4L^2} \pm \frac{r}{2L^2} = d = DH. \end{array} \right.$$

4. This Rule as it stands here whole, only answers to those Equations wherein are all the Terms p , q , and r ; and in the same time may also be easily accommodated to all other Cases, by observing these things. 1. Whatever Term, or Quantities p , q , r , be wanting in the proposed Equation, that must also be respectively omitted, or put out of the general Central Rule, that the remaining quantities may determine the special or particular Central Rule. 2. As for what belongs to the Signs, *viz.* whether \pm (which latter Sign denotes a dubious Case, either that the r must be subtracted from the latter, or contrary-wise, as the matter will bear) must be put in the Central Rule, he observes (a) that in the Rule you'll always have $\pm r$, unless $\frac{r}{2L^2}$

when in the proposed Equation p and r are affected with diverse Signs: (β) By what Sign soever in the proposed Equation it happens that the quantity q is marked with, it must be noted in the contrary one (altho' involv'd with other quantities) in the Rule; as may be seen in the application of the Rule to special Cases done by the Author himself for the sake of Beginners, and is exhibited in the Synopsis hereunto adjoining, which yet we have thought fit to give at the end of this Treatise, much more contract as to the Central Rules, in a short Appendix by way of Appendix.

5. By these Rules therefore, the quantities of the Lines aD and DH will be so determined, that the parts in the Equation marked with the Sign $+$ (taken either aggregately or separately) will be put downwards from a to A towards y , and on the left hand of D ; but the negative Parts, or those affected with the Sign $-$, will be cut off, on the one part above, on the other on the right hand: Which being done the Center H may be found.

6. From the Center H thro' the Vertex of the Axis a (if the Center D is found in the Axis) or in the other Case thro' the Center of the Diameter A , you must draw a Circle which by passing or touching the Parabola will determine the Roots sought,

C

sought, if the Equation be not a Biquadratick *i. e.* has not the quantity S ; otherwise another Point L or Z must be found, (*vid.* Fig. 12. and 13.) and a Circle described on the Radius HL or HZ , according to *Des Cartes* p. 86, and following, of his Geometry.

7. *Viz.* If you have— S , you must take on the Line Ha or HA produced, on the one side $AI = L$ or 1 , and on the other $AK = S$, and describing a Semi-circle on IK , draw AL
 $\underline{L^3}$

perpendicular to AH , to obtain the point L . (see Fig. 12.) But if you have $\dagger S$, then in another Semicircle described on AH , apply the Line $AZ =$ to AL found, thereby to obtain Point Z , (see Fig. 13.)

8. A Circle therefore described from H through a or A , if S be wanting, but thro' L if there be— S , and thro' Z if $\dagger S$, may touch or cut the Parabola either in 1, 2, 3 or 4 Points; from which if you let fall Perpendiculars to the Ax or Diameter, you will obtain all the Roots of your Equation both true and false.

9. And, 1. If in the Equation p be wanting and— r be there, the true Roots will be on the left side of the Ax , as NO , and the false ones as MO on the right side. 2. But if there be in the Equation p and— p , the true Roots will fall on the left side of the Diameter, and the false ones on the right; but if $\dagger p$, on the contrary the true will be on the right hand and the false on the left.

10. But if the Circle neither touches nor cuts the Parabola in any point, it is a sign that the Equation is impossible, and has no Root either true or false, but only imaginary ones. All which, how they may be found out, and that they are undoubtedly true, are demonstrated *a posteriori*, in an easie and plain way by the Author, wherefore we shall not give the Demonstrations of them here; but remit the Reader, after he has made a little progress in this Art, to the Author himself.

11. Wherefore now, (omitting also in this place the Doctrine of the Composition of the plain and solid Geometrical *Loci*, or Places, which would serve for a Complement of the Analytick Art) we will shew the Practice of these Rules already delivered, premonishing only this from Mr. Baker, if the *Latus Rectum* be made Unity, that L in the Central Rules
 and

and all its Powers may be omitted, and so the Rules exhibited more compendiously, as we have already done in our Synopsis, and may be seen from the form of a general Central Rule hereunto annexed.

$$\text{Part} \left\{ \begin{array}{l} 1. \frac{1}{2} + \frac{p^2}{8} + \frac{q}{2} = b = aD \text{ or } AD \\ 2. \frac{p}{4} + \frac{p^2}{16} + \frac{pq}{4} + \frac{r}{2} = d = DH. \end{array} \right.$$

To which Premonition of *Baker* we may also add this, if any given Line in the Problem it self be taken for Unity, which may be often very commodiously done [as *a* in the former Problem p. 91. *Geom. Cartes*, and the Line NO in the latter, and *a* again in the Equation p. 83. the last line] and then the same Line also may be taken for the *Latus Rectum* of the Parabola to be described, if we have a mind to make use of this Compendium for abbreviating the Central Rules. For otherwise if we would construct all Problems, as *Baker* rightly asserts we may, by only one Parabola, we shall fall often into very tedious Prolixities.

SOME

SOME
E X A M P L E S
O F
SPECIOUS ANALYSIS,

In each kind of Equations.

I. In Simple Equations.

PROBLEM I.

HAVING the sum of any two sides given for forming a Triangle *ABC*, to find each of the sides, and form the Triangle.

Suppose *e. g.* three Lines given in *Fig. 14.* the first = $AB + AC$ in the Triangle sought, the second = $AB + BC$, the third = $BC + AC$, to find each of the sides *e. g.* to find *AB*, which being known, the rest will be so also.

SOLUTION.

1. *Denomination.* Make $AC + AB = a$; $AB + BC = b$; $BC + AC = c$; $AB = x$; then will $AC = a - x$, and $BC = b - x$, and so the Denomination be compleat.

2. *Equation.* Now if the values of the two last Lines *BC* and *AC* be added into one Sum, which we had before given; you'll have this Equation $a + b - 2x = c$.

3. *Reduction.* By adding on both sides $2x$, you'll have
 $a + b = c + 2x$; and subtracting from
 both sides $c \dots a + b - c = 2x$; and dividing both
 sides by 2 $\dots \frac{a + b - c}{2} = x$.

$$\frac{2}{2}$$

4. The

4. The *Effect* or *Geometrical Construction*, which the Equation thus reduced will help us to

Join $AE = a$ and $ED = b$ in one Line AD , and from this backwards cut off $DF = c$; and divide AF which remains into two equal parts in B , and you'll have AB the first side of the Triangle to be formed; and BE will give the other side AC , which subtracted from ED , will leave $GD =$ to the third side BC ; of which you may now form the Triangle ABC .

5. A *general Rule* for *Arithmetical Cases*. Add the two former Sums, and from the Aggregate subtract the third Sum; half the Remainder will give the side AB common to the two former Sums. For an Example take this Question: There are three Towns of ancient *Hetruria*, viz. *Forum Cassii* (which the Letter A denotes in $\triangle ABC$) *Sudertum* (B) and *Volsinii* (C) which are at this distance one from another; if you go from *Volsinii* to *Forum Cassii* and thence to *Sudertum*, you must go 330 Furlongs; from *Forum Cassii* to *Sudertum* and thence to *Volsinii* there are 306 Furlongs; lastly, from *Sudertum* to *Volsinii* and thence to *Forum Cassii* 272 Furlongs. How far is each Town distant from each other.

PROBLEM II.

In a right-angled Triangle ABC , having given the Base AB , and the difference of the Perpendicular AC and the Hypothenusa BC to find the Perpendicular and Hypothenusa, and form the Triangle.

Make e , g , the Base AB (*Fig. 15.*) and the difference of the Perpendicular and Hypothenusa BD , to find the Perpendicular AC ; which being known, the Hypothenusa AC will be known also, if the given difference be added to the found Perpendicular.

SOLUTION.

1. *Denomination*. Make $AB = a$, $BD = b$, $AC = x$; then will $BC = x + b$.

2. *Equation* by the Pythagorick Theorem,

$xx + aa = xx + 2bx + bb$, viz. the two Squares of the Sides to the Square of the Hypothenusa,

3. *Reduction*

3. *Reduction.* Subtracting from both sides xx , you'll have
 $aa = 2bx + bb$; and moreover by subtracting also bb ,
 $aa - bb = 2bx$; and dividing by $2b$

$$\frac{aa - bb}{2b} = x.$$

4. *Effecton or Geometrical Construction.* Having described upon the given Base AB a Semi-circle, apply therein the given difference BD, and draw AD, whose Square is $= aa - bb$. Since this must be divided by $2b$, make, as $AE = 2b$ to $AD = \sqrt{aa - bb}$, so $AD = \sqrt{aa - bb}$ to AC the Perpendicular sought. To which if you add $CF = BD$, you will have $AF =$ to the Hypotenuse sought BC; which will come of course together with the whole Triangle sought, if the found Perpendicular AC be erected at right Angles on the given Base AB.

5. *The Rule for Arithmetical Cases.* From the square of the given Base subtract the square of the given difference, and divide the Remainder by the double difference; and you'll have the Perpendicular sought. E.g. suppose the Base $= 20$ foot, and the difference between the Perpendicular and Hypotenuse 10.

PROBLEM III.

IN the right angled Triangle ABC, having given the side AC and the sum of the other side AB and the Hypotenuse BC, to find the other side and the Hypotenuse separately, and form the Triangle. Suppose the given side (that is to be) AC (Fig. 16.) and the sum of the other sides AD, to find the side AB, which being known the Hypotenuse BC will be known also.

SOLUTION.

1. *Denomination.* Make $AC = a$, $AD = b$, $AB = x$, then will $BC = b - x$.

2. *Equation.* $xx + aa = bb - 2bx + xx$ and subtracting xx .

3. *Reduction.*

3. *Reduction.* $aa = bb - 2bx$; and adding $2bx$,
 $aa + 2bx = bb$; and subtracting aa ,
 $2bx = bb - aa$; and dividing by $2b$,
 $x = \frac{bb - aa}{2b}$.

4. The *Effect* or *Construction* is like the former, and so will be manifest only by inspecting that Scheme.

5. The *Arithmetical Rule*. From the square of the given sum subtract the square of the given side, and divide the Remainder by double the given sum; and you'll have the other side, and subtracting that from the given sum, you have the Hypotenuse also. E.g. let one side be 15, and the sum of the other two 45.

PROBLEM IV.

HAVING given the Perpendiculars and sum of the Bases of two right-angled Triangles having equal Hypotenuses, to find the Bases separately, and form the Triangles. Suppose e. g. to form the Triangle ABC (see Fig. 17.) you have given the Perpendicular AB, and for the other \triangle ADC, the Perpendicular CD, and the given sum of the Bases BE, to find the Bases singly, viz. the less for the greatest Perpendicular, and the greater AD for the less Perpendicular.

SOLUTION.

1. *Denomination.* Make $AB = a$, $CD = b$, the sum $BE = c$; make the lesser Base $BC = x$; the greater AD will $= c - x$.

2. *Equation.* Since the Hypotenuses of the two Triangles are supposed equal, the two $\square\square AB + BC$, i. e. $xx + aa$ will be $=$ to the two $\square\square AD + CD$, i. e. $bb + cc - 2cx + xx$.

3. *Reduction.* By taking away therefore xx and adding $2cx$, $aa + 2cx$ will $= bb + cc$; and further taking away from both sides aa , $2cx = bb + cc - aa$; and dividing both sides by $2c$, $x = \frac{bb + cc - aa}{2c}$.

4. *Geoms.*

4. *Geometrical Construction.* Join the Lines b and c . CD and BE at right Angles, (n. 2.) and the square of the Hypotenuse DE will $\equiv bb + cc$. Upon this Hypotenuse having described a Semi-circle, apply therein the Line AD, and the square of AE will $\equiv bb + cc - aa$. Which, since it may be further divided by $2c$, make (n. 3.) as $BF \equiv 2c$ to $BE \equiv \sqrt{bb + cc - aa}$, so BG to BC, the lesser Base sought.

5. *The Arithmetical Rule.* From the sum of the square of the lesser Perpendicular and the sum of the Bases subtract the square of the greater Perpendicular, and the Remainder divided by the double sum of the Bases, will give the lesser Base. E.g. make AB 76, CD 57, and BE 114.

PROBLEM V.

HAVING given the Perpendiculars of two right-angled Triangles standing on the same given Base, to find the Segments of the Hypotenuses. E. g. suppose the common given Base be AB (Fig. 18.) and the Perpendicular of one Triangle AD of the other BC; to find the segments of the Hypotenuses, cutting one another geometrically.

SOLUTION.

If a Geometrical Solution be required there is no need of any Analysis; for having erected perpendicularly on the common given Base AB the given Perpendiculars AD and BC, the Hypotenuses AC, BD being drawn immediately, exhibit their Segments EA, EB, EC, ED. But if it be to be done arithmetically by a general Rule, then an Analysis will be necessary.

1. *Denomination.* Make the common Basis $AB \equiv a$, $BC \equiv b$, $AD \equiv c$; and, having found AF, all the rest may be had (for as AB to BC so AF to FE; which being given, you have also GD and HC, and consequently also DE, CE, &c.) make $AF \equiv x$, then will BF or HE $\equiv a - x$.

2. *The Equation* from FE found twice.

1. As AB to BC so AF to FE.

$$a \text{ — } b \text{ — } x \text{ — } \frac{bx}{a}$$

2. As

XXIII

XXIII

XXIV

XXV

XXVIII

XXVI

XXVII

1. As BA to AD so BF to FE.

$$a \text{ --- } c \text{ --- } a \text{ --- } x \text{ --- } \frac{ac \text{ --- } cx}{a}$$

Therefore $\frac{bx}{a} = \frac{ac \text{ --- } cx}{a}$

2. *Reduction.* Multiplying both sides by a you'll have bx^2 , $ac \text{ --- } cx$; and adding on both sides cx , $bx^2 + cx = ac$ dividing both sides by $b + c$, $x = \frac{ac}{b+c}$

3. *The Arithmetical Rule.* Multiply the common base the least Perpendicular, and divide the Product by the sum the Perpendiculars; and you'll have the lesser segment of the AE , which being given you'll have all the rest. E g. sup. $AB = 10$, $BC = 9$, $AD = 6$.

PROBLEM VI.

To inscribe a Rhombus in a given Oblong, i. e. having the sides of the Oblong AB and BC given, (Fig. 19.) to find Segment BF or DE , which being cut off, the remainder FC or AE will be the side of the Rhomb sought.

SOLUTION.

Make $AB = a$, $BC = b$, $BF = x$: FC or FA will be $= a - x$ (so far the Denomination.) Therefore the square of FA , which is $bb - 2bx + xx$ will be $= aa + xx$, viz. to the two squares of AB and BF (so far the Equation:) and subtracting from both sides xx , $bb - 2bx = aa$; and
 $bb = aa + 2bx$, and
 $bb - aa = 2bx$; and
 $\frac{bb - aa}{2b} = x$. (so far the Reduction.)

The Geometrical Construction. Having described a semi-circle on BC (n. 2.) apply CD or AB , and the \square BD will be $bb - aa$. Which since it must be divided by $2b$, make, $DE = 2b$ to $BD = \sqrt{bb - aa}$, so BD to BF sought, and be cut off the side of the Oblong BC (n. 1.)

D d

The

The Arithmetical Rule. From the square of the greater side subtract the square of the lesser, and divide the remainder by double the greater side, and the quotient will give the Segment BF sought. E. g. suppose $AB = 4$, and $BC = 8$.

PROBLEM VII.

TO inscribe the greatest square possible in a given Triangle, i. e. having given the height of the Triangle CD (Fig. 20) and the Base AB, to find a portion of the altitude CE, which being cut off there shall remain $ED = FG$.

SOLUTION.

Make the base $AB = a$; the altitude $CD = b$, $CE = x$; then will ED or $FG = b - x$.

By reason of the similitude of the Triangles ABC and FGC you'll have as AB to CD so FG to CE.

$$a - b - b \cdot x - x$$

Therefore the Rectangles of the means and extremes will be equal, i. e. $ax = bb - bx$; and adding on both sides bx , $ax + bx = bb$, and dividing by $a + b$, $x = \frac{bb}{a+b}$.

Construction. Upon the side of the Triangle CB produced, make $CH = b$, and $HI = a$, so that the whole Line shall be $a + b$. And having joined ID and parallel to it HE drawn from H, the part CE will be cut off, which is that sought.

For as CI to CD so CH to CE,

$a + b - b - b - x$ according to the second case of simple Effections.

Arithmetical Rule. Square the given height of the Triangle, and divide the Product by the sum of the base and altitude; and the quote is the part to be cut off CE. E. g. suppose $CD = 10$, and $AB = 15$.

PROBLEM VIII.

IN an acute-angled Triangle having all the sides given, find the Perpendicular that shall fall from the Vertex on the Base, i. e. having given AB, AC, BC (Fig. 21.) to find AD

or BD (for having found the one you may easily find the other) Coroll. Prop. 13. Lib. 2. Eucl.

S O L U T I O N.

If there be only required a Geometrical Construction of this Problem, there will be no need of any Analysis; for having formed a Triangle ABC of the three given sides, you need only let fall the perpendicular AD from the Vertex A, which would determine the Segment BD. To find the general Arithmetical Rule, which is the general Corollary of Euclid, or if any one for exercise sake had rather determine the Perpendicular DA by the segment of the Base BD, than the latter by the former, the Analysis will proceed thus:

Make $AB = a$, $BC = b$, $AC = c$, $BD = x$; then will $CD = b - x$. Wherefore by the Pythagorick Theorem $AD^2 = aa - xx$, and by the same reason the same $AD^2 = cc - bb + 2bx - xx$. Therefore $ax - xx = cc - bb + 2bx - xx$; and by adding on both sides xx , $ax = cc - bb + 2bx$; and by transferring $cc - bb$, $ax - cc + bb = 2bx$, and dividing by $2b$, $\frac{ax - cc + bb}{2b} = x$.

The Arithmetical Rule. Subtract the square of the lesser side from the Sum of the $\square\square$ of the base and greater side, and the remainder divided by double the base will give its greater segment: If the \square of the greatest side be subtracted from the sum of the other squares, &c. you will have the less segment CD.

Geometrical Construction Having described a semi circle upon AB (n. 2.) apply therein AC, and the \square BC will $= aa - cc$, and continuing AC to B, till CB be $= CB$ (n. 1.) the \square of BB will $= aa - cc + bb$; which since it is to be divided by $2b$ make as BE $= 2b$ to BB $= \gamma$ $aa - cc + bb$, so BF $= BB$ to BD the segment sought $= BD$ n. 1.

P R O B L E M IX.

IN an obtuse angled Triangle having the three sides given to find the Perpendicular let fall from the Vertex to the Base being continued: i. e. Having given AB, BC, AC (Fig. 22. n. 1.) to find AD or CD (for the one being found the other will readily be so also) Coroll. Prop. 12. Lib. 2. Eucl.

D d 2

S O L U -

S O L U T I O N.

What we premonish'd about the former Problem, we understand to be premonish'd here also. For the rest make here also $AB \sqcap a$, $BC \sqcap b$, $AC \sqcap c$, $CD \sqcap x$; then will $BD \sqcap b + x$: Wherefore by the Pythagorick Theorem the $\square AD$ will $\sqcap cc - xx$, and by the same Theorem the same $\square AD \sqcap aa - bb - 2bx - xx$.

Therefore $cc - xx \sqcap aa - bb - 2bx - xx$; and adding to both sides $cc \sqcap aa - bb - 2bx$; and transposing cc and $-2bx$, $2bx \sqcap aa - cc - bb$; and dividing by $2b$, $x \sqcap \frac{aa - cc - bb}{2b}$.

The Arithmetical Rule. Subtract from the square of the greater side the sum of the squares of the base and lesser side; and the Remainder divided by double the base will give its continuation to the Perpendicular.

Geometrical Construction from the Equation reduc'd: Having described a semi-circle upon AB (n. 2.) apply therein AC , and the \square of CB drawn will $\sqcap aa - cc - bb$; which since it must be divided by $2b$ make, as $CF \sqcap 2b$ to $CE \vee aa - cc - bb$, so CE to CD the segment sought, n. 1.

P R O B L E M X.

Commonly ascribed to Archimedes.

THE Diameter AB of a given semi-circle (Fig. 22. n. 1.) being any how divided in L , and from L erecting a Perpendicular LX , and upon the segments LA and LB having described two other semi-circles, whose semi-diameters are also given as well as that of the great Circle CB ; to find the Radii FM and Vy of the little Circles that are to be so described, that they shall touch the Perpendicular LX , the Cavity of the greater semi-circle, and the Convexities of the less.

S O L U T I O N.

S O L U T I O N.

I. For the Radius FM.

1. *Denomination.* Make $CB = a$, $EB = b$ then will $CE = a - b$; for which for brevities sake put c . And let FM or FN or $FK = x$: Therefore EF will be $= b + x$, and CF (subtracting FK from CK) $= a - x$. Wherefore now you'll have at least the names of the three sides in the $\triangle CFE$, so that according to Pöblem 8. the Segment of the base GE may be determined (which indeed is determined already, as being $= LE - LG$ or MF i. e. $b - x$) for which in the mean time we will put y ; and now will $CG = c - y$.

2. For the Equation. If the $\square GE = y$ be subtracted from the $\square EF = bb + 2bx + xx$, you'll have the square of the Perpendicular $FG = bb + 2bx + xx - yy$; and, if $\square CG = c - 2cy + yy$ be subtracted from the $\square CF = aa - 2ax + xx$, you'll have the same \square of the Perpendicular $FG = aa - 2ax + xx - cc + 2cy - yy$. Therefore $bb + 2bx + xx - yy = aa - 2ax + xx - cc + 2cy - yy$.

3. *Reduction.* And taking from both sides the quantities xx and yy , $bb + 2bx = aa - 2ax - cc + 2cy$; and adding $2ax$ and cc , but taking away aa from both sides, $bb + 2bx = aa - 2ax - cc + 2cy$; and adding $2ax$ and cc , and taking away from each side aa , $bb + 2bx + 2ax + cc - aa = 2cy$; and dividing by $2c$,

$$\frac{bb + 2bx + 2ax + cc - aa}{2c} = y.$$

but the same y or EG is $= EL - MF$ i. e. $b - x$. Therefore $\frac{bb + 2bx + 2ax + cc - aa}{2c} = b - x$;

which is a new and more principal Equation: And multiplying both sides by $2c$ (you have a new Reduction) $bb + 2bx + 2ax + cc - aa = 2ac - 2bx$; and adding $2cx$, and transposing the others, $2bx + 2cx + 2ax = aa - bb - cc + 2bc$; and dividing by $2a + 2b + 2c$,

$$\frac{x = aa - bb - cc + 2bc}{2a + 2b + 2c}.$$

The

The Geometrical Construction of this first Case. Add the determinate (*n* 2.) quantity $2bc$ into one sum with the quantity aa , as in the beginning, *n* 3. Then from this sum subtract successively the quantities bb and cc , and there will come out (the same *n* 3) FH , whose $\square = aa + 2bc - bb - cc$. Which since it must be divided by $2a + 2b + 2c$, make (the same *n* 3) as $FI = 2a + 2b + 2c$ to $FH = \sqrt{aa + 2bc - bb - cc}$, so FH to FM the Radius sought of the little Circle to be described. This quantity FM being thus found, place it from L to G (*n* 1.) and from G erect a Perpendicular, which being cut off at the interval CF (which may be had, if from CB or CK you cut off $FK = FM$) or from E at the interval EF (which is composed of the Radii EN and FN) gives the Center of the little Circle to be described.

The Arithmetical Rule. Add twice the \square CEB to the square of the greatest semi-diameter CB , and from the sum subtract the Aggregate of the \square CE and EB ; divide the remainder by the sum of all the three Diameters, (AB , AL and LB) *i. e.* by double the greatest AB ; and you'll have the Radius FM , &c. For Example sake let a be $= 12$, $b = 4$; c will be $= 8$, and x will be produced $= 2\frac{2}{3}$.

II. For the Radius Vy by help of the obtuse-angled $\triangle DFC$.

1. *Denomination.* $CA = a$ as above, DA or $DL = b$, and putting x again for the sought Vy or VK , CV will be $= a - x$, DL or $DR = b$, and consequently $DV = b + x$, and $DC = a - b$, for which for brevity's sake we will put c . Now you'll have at least in Denomination in the $\triangle CVD$ the three sides, so that according to Problem 9. the segment CW may be determined, for which in the mean while we will put y ; then will $DW = c + y$, which is the same as $DL - WL$ or Vy *i. e.* $b - x$.

2. For the Equation. If the \square $CW = yy$ subtract it from the \square $CV = aa - 2ax + xx$, and you'll have the \square of the Perpendicular VW , $aa - 2ax + xx - yy$; and if the \square $DW = cc + 2cy + yy$, subtract it from the \square $DV = bb + 2bx + xx$, and you'll have the same \square of the Perpendicular $VW = bb + 2bx + xx - cc - 2cy - yy$. Therefore

$$aa - 2ax + xx - yy = bb + 2bx + xx - cc - 2cy - yy$$
 3. *Redu-*

3. *Reduction.* Therefore taking from both sides xx and yy ,
 $aa - 2ax = bb + 2bx - cc - 2cy$; and adding $2cy$
 and $2ax$, $aa + 2cy = bb + 2ax + 2bx - cc$; and subtract-
 ing aa , $2cy = bb - aa + 2ax + 2bx - cc$, and dividing
 by $2c$,

$$y = \frac{bb - aa + 2ax + 2bx - cc}{2c}$$

But if you add to the same y or CW $DC = c$, you'll have

$$DW = \frac{bb - aa + 2ax + 2bx - cc + c}{2c} \text{ i. e.}$$

reducing this c to the same Denomination,

$$\frac{bb - aa + 2ax + 2bx + cc}{2c} = DW. \text{ But the same } DW$$

$$= DL - WL = \frac{b - x}{2c}. \text{ Therefore}$$

$$\frac{bb - aa + 2ax + 2bx + cc}{2c} = b - x, \text{ and multiplying}$$

x , $bb - aa + 2ax + 2bx + cc = 2^1c + 2cx$, and adding
 xx , and transposing the rest, $2ax + 2bx + 2cx = aa - bb$
 $- cc + 2bc$, and dividing by $2a + 2b + 2c$,

$$x = \frac{aa - bb - cc + 2bc}{2a + 2b + 2c} \text{ just as above in}$$

the first Case.

4. *The Geometrical Construction* therefore will be the same
 as there. See Fig. 23. n. 4. and 5.

5. *The Arithmetical Rule* is also the same, but the given
 quantities in this Example, which the figure of the Problem
 will shew, thus vary, while a remains 12, b will be 8, and
 c 4, from which *data* (or given quantities) there will not-
 withstanding come out again, for x or the Radius Vy $2\frac{2}{3}$.

II. Some

II. Some Examples of simple or pure Quadratick Equations.

PROBLEM I.

TO make a Square equal to a given Rectangle; i. e. having given the sides of the Rectangle, to find the side of an equal Square, Eucl. Prop. 14. Lib. 2. Suppose e. g. the given sides of the Oblong to be AB and BC (Fig. 24) to find the Line BD whose square shall be equal to that Rectangle.

SOLUTION.

Make $AB = a$ and $BC = b$, and the side of the square sought $= x$, and the Equation will be $ab = xx$; and extracting the root on both sides $\sqrt{ab} = x$.

Geometrical Construction. Join AB and BC in one right line, and describing a semi-circle upon the whole AC, from the common juncture B erect the Perpendicular BD which will be the side of the square sought, according to Case 1. of the Effect of pure quadratics.

Arithmetical Rule. Multiply the given sides of the Oblong by one another, and the square root extracted out of the Product will be the side of the square sought.

PROBLEM II.

THE square of the Hypotenusa in a right-angled \triangle being given, as also the difference of the other two squares to find the sides. E. g. If the Hypotenusa be BC (Fig. 25) and the difference of the squares of both the legs, and consequently its Leg also BE given (for the squares being given the sides are also given geometrically) to find the sides of the right-angled \triangle which shall have these conditions; or more plainly, to find one side e. g. the lesser which being found, the other, or the greater, will be found also.

S O L U T I O N.

Let the \square of the given Hypothenusa $= aa$, and the square by which the two other differ $= bb$. Let the less side $= x$, and its $\square = xx$. Wherefore the greater will be $xx + bb$. And since the sum of these is $=$ to the \square of the Hypothenusa, you'll have

$$2xx + bb = aa; \text{ and subtracting } bb,$$

$$2xx = aa - bb; \text{ and dividing by } 2$$

$$xx = \frac{aa - bb}{2}. \text{ Therefore}$$

$$x = \sqrt{\frac{aa - bb}{2}}.$$

Geometrical Construction. Having described a semi-circle on BC, and applyed therein BE, the \square EC will $= aa - bb$; and having described another semi circle upon EC divided into two Quadrants the \square DC will be $\frac{aa - bb}{2}$, and so DC $= \sqrt{\frac{aa - bb}{2}}$,

or the side sought; which being also transferr'd upon the other semi-circle describ'd on BC, viz. from C to A gives the other side AB and the whole \triangle sought.

The Arithmetical Rule. From the square of the Hypothenusa subtract the given difference, and the square root extracted out of half the remainder gives the lesser side of the \triangle sought.

P R O B L E M III.

Having an equilateral $\triangle ABC$ given (Fig. 26. n 1.) to find the Center and Semi diameter of a Circle that shall circumscribe it. i. e. Find the BD the side of an Hexagon that may be inscribed in it. For if we consider the thing as already done; it will be manifest that the side of the Hexagon BD will fall perpendicularly on the side of the \triangle AB, as making an angle in a semi-circle, so having bisected the Hypothenusa DA you'll have E the Center sought.

S O L U T I O N.

Make the side of the Triangle $AB \equiv a$, $BD \equiv x$, then will $AD \equiv 2x$. Since therefore the square BD i. e. xx being subtracted out of the square AD i. e. $4xx$, there remains the square AB $3xx$, you'll have the Equation

$$3xx \equiv aa; \text{ and dividing by } 3$$

$$xx \equiv \frac{aa}{3}; \text{ therefore}$$

$$x \equiv \sqrt[3]{\frac{aa}{3}}$$

The Geometrical Construction. Having produced AB (n. 2.) to F a third part of it, the square of a mean proportional BD between BF and BA will be $\frac{1}{3}aa$ or $\frac{aa}{3}$, and so the Line BD

$$\equiv \sqrt[3]{\frac{aa}{3}}. \text{ Therefore the Hypothenusa } DA \text{ being divided in}$$

two in E , or at the interval BD , making the intersection from B and A , you'll have the Centre sought.

The Arithmetical Rule. Divide the square of the given side into three equal parts, and the square Root of a third part will give the semi-diameter AE or BE sought, by the intersection of two of which you'll have the Centre.

P R O B L E M I V.

HAVING given, in a right-angled Parallelogram, the Diagonal, or for a right-angled Δ , the Hypothenusa and the proportion of the sides, to find the sides separately and construct the Parallelogram or Δ . Suppose e. g. the given Diagonal to be AB (Fig. 27. n. 1.) and the given reason of the sides as AD to DE , to find the sides.

S O L U T I O N.

Make $AB \equiv a$, the reason of AD to DE as b to c ; make the lesser side $\equiv x$, then will the greater be $\frac{cx}{b}$.

For the Equation, the $\square \square$ of the sides are $xx + \frac{ccxx}{bb} = aa$,

$\square AB$; and multiplying both sides by bb ,
 $bbxx + ccxx = aabb$; and dividing by $bb + cc$,
 $xx = \frac{aabb}{bb + cc}$. Therefore

$$x = \frac{\sqrt{aabb}}{\sqrt{bb + cc}} \text{ i. e. Extracting the roots as far as possible}$$

$$x = \frac{ab}{\sqrt{bb + cc}}$$

Another Solution.

Call the name of the given reason e , so that assuming any line for unity, the value of e may also be expressed by a right line, which shall be equal e . g. to DE above. Wherefore because we make the less side x , the greater will be ex , and so

$$xx + eexx = aa, \text{ i. e. dividing by } 1 + ee,$$

$$xx = \frac{aa}{1 + ee}$$

$$x = \frac{\sqrt{aa}}{\sqrt{1 + ee}}, \text{ i. e.}$$

$$x = \frac{a}{\sqrt{1 + ee}}$$

The Geometrical Construction. The last Equation above being reduc'd to this proportion as the $\sqrt{bb + cc}$ to b so a to x , make $(n. 2.)$ AD and DE at right angles, and AE will be $= \sqrt{bb + cc}$, and continuing AE and AD make as AE to AD so AB to AC the lesser side sought. Having therefore drawn BC which determines the lesser side AC , the greater side and so the $\triangle ABC$ will be already formed, and may be easily compleated into a Rectangle. In the other Solution the last Equation agrees with the precedent (for it gives us this proportion as $\sqrt{1 + ee}$ to 1 so a to x in which 1 is $= b$, and $ee = cc$ by what we have supposed) and so the Construction will be the same.

The *Arithmetical Rule* may be more commodiously expressed by this last Equation under the last form but one, after this way, divide the \square of the Diagonal by the \square of the name of the Reason lessen'd by unity, and the root extracted out of the Remainder is the lesser side sought.

PROBLEM V.

(Which is in *Pappus Alexandrinus*, and in *Carter's Geometry*, p. 83. in a Biquadratick affected Equation, and p. 84. he gives us thereon a very remarkable Note.)

HAVING given the Square *AD* (Fig. 28) and a right line *BN*, you are to produce the side *AC* to *E*, so that *EF* drawn from *E* towards *B* shall be equal to *BN*.

It will be evident, if you imagine a semi-circle to pass thro' the points *B* and *E*, that the most commodious way will be to find the line *DG*, that you may have the Diameter *BG*; upon which having afterwards described a semi circle, there will be need of no other operation to satisfy the question, than to produce the side *AC* till it occur to the prescrib'd Periphery.

SOLUTION.

(As found by Van Schooten, p. 316. in his *Comment on Cartes's Geometry*, which we will here give somewhat more distinct.)

1. *Denomination.* Make *BD* or *DC* $\equiv a$, *BN* or *FE* $\equiv c$, *BF* $\equiv y$, and *LG* $\equiv x$; the Perpendicular *EH* will be $\equiv a$, and *EG* $\equiv BF$, viz. y (because the $\triangle EHG$ is similar to $\triangle EDF$, by n. 3 Schol 2 Prop 34. Lib. 1. *Mathes. Encl.* and *BD* in the one \equiv to *EH* in the other) and *BG* $\equiv a + x$, *BE* $\equiv y + c$; and *BH* will have its Denomination, if you make (by reason of the similarity of the $\triangle BFD$ and $\triangle EHF$)

as BF to BD so BE to BH

$$y \text{ --- } a \text{ --- } y \dagger c \text{ --- } \frac{ay \dagger ac}{y}$$

and you'll have also $HG = a \dagger x \text{ --- } \frac{y}{ay \text{ --- } ac}$, i. e. having

reduc'd them all to the same Denomination,

$$\frac{ay \dagger xy \text{ --- } ay \text{ --- } ac}{y}, \text{ i. e. } \frac{xy \text{ --- } ac}{y}. \text{ Having therefore nam'd all the lines you have occasion for, you must find two Equations, because there are assumed two unknown quantities, viz. } x \text{ and } y.$$

2. For the first Equation and its Reduction. By reason of the familiarity of the $\triangle BGE$ and BEH ,

as BG to GE so BE to EH

$a \dagger x \text{ --- } y \text{ --- } y \dagger c \text{ --- } a$: Therefore the Rectangle of the Extremes will be $=$ to the Rectangle of the means,

i. e. $yy \dagger yc = aa \dagger ax$; and taking from both sides yc ,

$$yy = aa \dagger vx \text{ --- } yc.$$

3. For the second Equation and its Reduction. Since

BH, HE and HG

$\frac{ay \dagger ac}{y} \text{ --- } a \text{ --- } \frac{xy \text{ --- } ac}{y}$ are continual proportionals, the

Rectangle of the extremes are equal to the square of the mean,

i. e. $\frac{axy \dagger acxy \text{ --- } aacy \text{ --- } aacc}{yy} = aa$; and multiplying

both sides by yy , and dividing by a

$xyy \dagger cxy \text{ --- } acy \text{ --- } acc = ayy$, and taking away ayy and transposing the rest,

$xyy \text{ --- } ayy = acy \text{ --- } cxy \dagger acc$; and dividing by $x \text{ --- } a$

$yy = \frac{acy \text{ --- } cxy \dagger acc}{x \text{ --- } a}$; i. e. dividing actually as far as may

be by $x \text{ --- } a$, $yy = \text{---} cy \dagger \frac{acc}{x \text{ --- } a}$.

4. The comparison of these two Equations thus reduc'd gives a third new one, in which there will be only one unknown quantity, viz.

$\text{---} cy \dagger aa \dagger ax = \text{---} cy \dagger \frac{acy}{x \text{ --- } a}$; and adding to both sides cy ,

$$x \text{ --- } a$$

$aa \dagger ax \equiv \frac{acc}{x-a}$; and multiplying by $x-a$,

$aax \dagger axx - a^3 - aax \equiv aac$; i. e. $axx - a^3 \equiv ac$
and dividing both sides by a , $xx - aa \equiv cc$; and adding
 $xx \equiv aa \dagger cc$. Therefore $x \equiv \sqrt{aa \dagger cc}$.

5. *The Geometrical Construction*, which is the same *Pappus* prescribes in *Cartes*, viz. having prolong'd the side of the square BA to N, so that BN shall be \equiv to a given right line, since BA is $\equiv a$, and BN $\equiv c$, the Hypotenuse DN will be $\equiv \sqrt{aa \dagger cc} \equiv x$. Having therefore made DG \equiv DN, and describ'd a semi-circle upon the whole line BG, if AC be prolonged until it occur to the Periphery in E, you'll have done that which was requir'd.

PROBLEM VI.

(Which *Van Schooten* has in his *Comment*,
p. m. 150, and following.)

HAVING given a right line AB, from the ends of it A and B (Fig. 29.) to inflect two right lines AC and BC, which shall contain an angle ACB \equiv to the given one D, and whose squares shall be in a given proportion to the Triangle ACB, viz. as 4d to a.

Viz. You must determine the point C, which the two right lines AH and HC or EH and HC will do, assuming the middle point E in the line AB. Wherefore here will be two unknown quantities HE and HC, and consequently two Equations to be found in the Solution; one whereof the given proportion in the Question supplies us with, and the other we have from the similar Triangles AIC and GFD, which represent equal angles.

SOLUTION.

Denomination. Make AE, half AB $\equiv a$, HE $\equiv x$ and HC $\equiv y$; therefore AH will be $\equiv a - x$ and HB $\equiv a \dagger x$; whence the Denomination of the squares AC and BC is easily had; viz. the one $aa - 2ax \dagger xx \dagger yy$, and the other, $aa \dagger$

n. 3, .

XXXII

n. 2, .

XXXIII

† $xx + yy$, so that the sum of the squares is $2aa + 2xx +$

And the $\triangle ACB$ will be $\equiv ay$: And since the $\triangle \triangle$
 D and $AI C$ are similar, and the sides of the former FD and
 arbitrary, so that for FD we may put b and for FC , c ;
 the sides of the latter are determined by the similitude of
 $\triangle \triangle ABI$ and HDB , as being right-angled ones, and ha-
 ving the common angle B ; they will be obtain'd by making
 the Hypoth. BC to the Hypoth. AB so the base HB to
 base BI , i. e.

$$e = 2a - a + x = \frac{2aa + 2ax}{e},$$

whence subtracting $BC \equiv e$, there remains $CI \equiv$
 $\frac{2aa + 2ax - ee}{e}$.

For the first Equation, by virtue of the Problem as 4d
 so $2aa + 2xx + 2yy$ to ay . And the Rectangle of the
 means is \equiv to the Rectangle of the means, i. e. $4ady \equiv 2a^3$
 $+ 2axx + 2ayy$.

For the other Equation, since
 as DF to FG so CI to AI

$$b - c = \frac{2aa + 2ax - ee - 2ay}{e}$$

the Rectangle of the extremes will again be \equiv to the Re-
 angle of the means, i. e. $\frac{2ayb}{e} \equiv \frac{2aac + 2acx - eec}{e}$;

multiplying both sides by e , $2ayb \equiv 2aac + 2acx - eec$;
 which is the second Equation.

The Reduction of both Equations.

The first was $4ady \equiv a^3 + 2axx + 2ayy$.

Therefore dividing by $2a$, $2dy \equiv aa + xx + yy$.

Subtracting $aa + yy$, $2dy - aa - yy \equiv xx$.

The latter Equation was $2ayb \equiv 2aac + 2acx - eec$, i. e.

Substituting again the value ee , which was

$2a + 2ax + xx + yy$.

$2ayb \equiv 2aac + 2acx - aac - 2acx - cxx - cyy$;

$2ayb \equiv aac - cxx - cyy$; and by transposition,

$cxx \equiv aac - 2ayb - cyy$; and dividing by c ,

$xx \equiv \frac{aa - 2ay - yy}{c}$, or $aa - yy - \frac{2ayb}{c}$,

or

or (putting $2f$ for $\frac{2ab}{c}$) $xx = aa - yy - 2fy$.

Wherefore we have the value of xx twice expressed, but by quantities partly unknown, because y is found on both sides. Wherefore now we must make a new comparison of their values, whence you'll have this new

5. *Third Equation*, in which there is only one of the unknown quantities:

$2dy - aa - yy = aa - yy - 2fy$; and adding on both sides both yy and aa ,

$2dy = 2aa - 2fy$; or dividing by 2,

$dy = aa - fy$; and transposing fy ,

$dy + fy = aa$; and dividing by $d + f$,

$y = \frac{aa}{d+f}$; which is the value of the quantity y in

known terms.

But this value in one of the precedent Equations, *viz.* in this $xx = 2dy - aa - yy$, being substituted for y and its square for yy , will give

$$xx = \frac{2daa - aa - a^4}{d+f}$$

to the same denomination,

$$xx = \frac{aadd - aaff - a^4}{dd + 2df + ff}; \text{ i. e. all being reduced}$$

$$x = \sqrt{\frac{aadd - aaff - a^4}{dd + 2df + ff}}.$$

6. *The Geometrical Construction*, which Schooten gives us p. 153. Having made the angle KAB (*n. 2. Fig. 29.*) equal to the given one D, erect from A, AL perpendicular to KA, meeting the Perpendicular EM in L; and from the Centre L, at the interval of the given right line d , describe a Circle that shall cut KA and EL produced to K and M. Then assuming EN = KA, join MA, and from N draw NH parallel to it, which shall meet AB in H. Afterwards, having described from L, at the interval LA, the segment of a Circle ACB, draw from H, HC perpendicular to AB meeting the circumference in C, and join AC, CB.

NB. The

NB. The reason of this elegant Construction, which the Author conceal'd, for the sake of Learners we will here shew: 1. Therefore, he reduc'd the last Equation (extracting the root, as well as it could bear, both of Numerator and Denominator) to this: $x = \frac{a}{d+f}$ multipl. by $\sqrt{dd-ff-aa}$, so

that after this way the Construction would be reduc'd to this proportion, as $d+f$ to a so $\sqrt{dd-ff-aa}$ to x . 2. He made the angle KAE = to the given one D, and the angle KAL a right one, so that having described the segment of a Circle from L the inscribed angle will also be made equal to the given one, according to the 33. Lib. 3: Eucl. 3. By doing this, EL expresses the quantity f , since by reason of the similarity of the $\triangle KOA$ f. GFD, n. 1. and AEL (for the angles LAE and AKO are equal, because each makes a right one with the same third Angle KAO) you have

$$\text{as KO to OA so AE to EL i. e. } f$$

$$\frac{c}{b} = \frac{a}{ab} = \frac{ab}{c}$$

4. Making now LM and LK = d you had EM = $d+f$, and AK = $\sqrt{dd-ff-aa}$ (for the \square AL is = to $aa+f$, which being subtracted from \square LK = dd , there remains \square AK = $dd-aa-ff$.)

5. Wherefore there now remains nothing to construct the last Equation above, but to make EN = AK, and to draw HN parallel to AM; for thus was the whole proportion as EM to EA so EN to EH

$$d+f-a-\sqrt{dd-ff-aa} \text{ to } x. \text{ Q. e. f.}$$

For the point H being determined, a perpendicular HC thence erected in the segment already described defines the Point C, which answers the Question.

PROBLEM VII.

Having given the four sides of a Quadrangle to be inscribed in a Circle, to find the Diagonals and their Segments, and so to construct the Quadrangle, and inscribe it in the Circle. As e. g. suppose the given sides are AB, BC, CD, DA (Fig. n. 1.) which now we suppose to be joined into a quadrangle

F f

gle

gle inscrib'd in the Circle, the Diagonals also AC and BD being drawn (*n. 3.*) to find first the segments of the diagonals Ae, Be, &c. which being had, the Construction is ready.

S O L U T I O N.

Denomination. Make $AB = a$, $AC = b$, $CD = c$, $DA = d$, $Ae = x$ [for this segment alone being found, the rest will be found also, as will be evident from the process.] Since therefore the vertical angles at *e* are equal, and likewise the angles in the same segment BCA, BDA, also DAC, DBC, &c. are equal, the Triangles AeD and BeC, also AeB and CeD are similar: wherefore it will follow that,

1. As DA to Ae so CB to Be

$$d \text{ --- } x \text{ --- } b \text{ --- } \frac{bx}{d}$$

2. As AB to Be so CD to Ce

$$a \text{ --- } \frac{bx}{d} \text{ --- } c \text{ --- } \frac{bcx}{ad}$$

3. As AB to Ae so CD to De

$$a \text{ --- } x \text{ --- } c \text{ --- } \frac{cx}{a}$$

Therefore the whole Diagonal AC will be $= x + \frac{bx}{d}$

and BD $= \frac{bx}{d} + \frac{cx}{a}$

2. *The Equation.* But now by *Prop. 48. Lib. 1. Math. Enucl.* the Rectangle of the Diagonals is equal to the two Rectangles of the opposite sides.

Diag. AC, $x + \frac{bx}{d}$

Diag. BD, $\frac{bx}{d} + \frac{cx}{a}$

$$\frac{cax + bcbx}{a \quad add}$$

Therefore

Therefore
the \square of the Diagonals $\frac{bxx}{d} + \frac{cxx}{a} + \frac{bbcxx}{add} + \frac{bccxx}{aad}$ is
 $= ac + bd.$

3. Reduction, i. e. taking (a) for unity

$$\frac{bxx}{d} + \frac{cxx}{a} + \frac{bbcxx}{dd} + \frac{bccxx}{d} = c + bd;$$

i. e. the quantities on the left hand being reduc'd to the same denomination.

$$\frac{bdxx + cddxx + bbcxx + bccdx}{dd} = c + bd;$$

and multiplying both sides by dd,

$$bdxx + cddxx + bbcxx + bccdx = cdd + bdd^3;$$

and dividing both sides by d

$$bxx + cxx + \frac{bbcxx}{d} + bccxx = cd + bdd;$$

and then dividing both sides by $b + cd + \frac{bbc}{d} + bcc,$

$$xx = \frac{cd + bdd}{b + cd + \frac{bbc}{d} + bcc}; \text{ i. e. in the present case, where}$$

b by chance happens to be = a,

$$xx = \frac{cd + dd}{1 + cd + \frac{c}{d} + cc}$$

$$\text{Therefore } x = \sqrt{\frac{cd + bdd}{b + cd + \frac{bbc}{d} + bcc}}$$

or in our case

$$x = \sqrt{\frac{cd + dd}{1 + cd + \frac{c}{d} + cc}}$$

4. The Geometrical Construction, which, by supposing a
(and in the present case also b) to be unity, ought to deter-

mine, 1. The quantities cd , $\frac{c}{d}$, cc , and their aggregate with

unity. 2. The aggregate of cd and dd . 3. To divide the one by the other. And, 4. To extract the root out of the quotient, or also to extract the roots first out of each quantity, and divide them by one another; which may all of them be separately done in so many separate Diagrams, but more elegantly connected together after the following or some such like way. 1. Join AD and DC (*n.* 2.) into one line, and having described a semi-circle thereupon, erect the Perpendicular DE; and the line AE drawn will $\equiv \sqrt{cd + dd}$. 2. Making the angle CAG at pleasure, make AF \equiv AB, and draw CG parallel to the line DF; so FG will be $\equiv \frac{c}{d}$. Now if, 3. in

the vertical angle you make AH \equiv CD, the line HI drawn parallel to DF will cut off AI $\equiv cd$. 4. In AK erected \equiv to AB, if you take AL \equiv AH or CD, and draw LM parallel to KH, you'll have AM $\equiv cc$. 5. Having prolonged AG to N and AH to O, so that GN shall be $\equiv AI + AM$ and AO \equiv AB or AK, and having described a semi-circle upon the whole line NO, a perpendicular erected AP will be $\equiv \sqrt{1 + cd + \frac{c}{d} + cc}$; and so, 6. if AQ be made \equiv AE

and AR \equiv AF or AB, and you draw a line RS from R parallel to PQ; AS will be $\equiv x$, *i. e.* the segment sought Ae of the Diagonal AC; which being given, by force of the first Inference premis'd in the Denomination above, by drawing DS and, having made DT \equiv BC, TV parallel to it; you'll have also the other segment Be \equiv SV and by their Interfection on the line AB (*n.* 3.) the point *e*, thro' which the Diagonals must be drawn which will be terminated by the other given sides, and thence you'll have the quadrilateral figure ABCD sought, to be circumscribed about the Circle, according to *Corsect. 6 Defin. 8. Mathes. Enucl.*

NB. Unless we had here consulted the Learner's ease, the artifice of this Construction might be proposed after a more short and occult way, thus: Make DE a mean proportional between AD and DC, and draw AE. Then having made any angle CAG, make AF \equiv AB, and at this Interval describe

scribe the circle FROK, and draw CG parallel to DF. Moreover in the opposite vertical angle, having made $AH = CD$, draw HI parallel to DF, and having erected the perpendicular AK, and thence the abscissa $AL = AH$, make LM parallel to HK, and thence having prolonged AH to O, and GN being made equal to $AI + AM$, make AP a mean proportional between AO and AN, cutting the hidden circle in R; and lastly having made $AQ = AE$, if RS be drawn parallel to QP, you'll have AS the value of x sought, &c.

III. Some Examples of Affected Quadratick Equations.

PROBLEM I.

Having given, to make a right angled Triangle ABC, the differences of the lesser and greater side, and of the greater, and the Hypotenusa, to find the sides separately and form the Triangle. E. g. Having given the right line DB (Fig. 31.) for the difference of the perpendicular and base, and CE for the difference of the base and Hypotenusa, to find the perpendicular AC, which being found, you'll have also by what we have supposed, the base AB, and the hypotenuse BC.

SOLUTION.

Make the difference $DB = a$, $CE = b$; put x for the perpendicular; the base, which is greater than that will be $x + a$ and the Hypotenusa $x + a + b$. Therefore by virtue of the Pythagorick Theorem,

$$2xx + 2ax + aa = xx + 2ax + 2bx + aa + 2ab + bb;$$

and subtracting from both sides $xx + 2ax + aa$,

$$xx = 2bx + 2ab + bb.$$

Wherefore by the first case of affected quadratick Equations

$$x = b + \sqrt{2ab + 2bb}.$$

Construction. Find a mean proportional AK between $AH = 2b$ and $AI = a$ (n. 2.) (Fig. 31.) and having made both AF and AG = b , place the Hypotenusa KF from AL, and cut

cut off GC equal to the hypotenuse GL; thus you'll have AC the perpendicular of the Triangle sought, and adding DB you'll also have the base AB, and from thence having drawn the hypotenuse BC, it will be found to differ by the excess required CE.

The Arithmetical Rule. Join twice the product of the differences multiplied by one another, to twice the square of the difference of the base and the hypotenuse; and if the square root of this sum being extracted be added to the aforesaid difference, you'll have the perpendicular sought. Suppose e. g. both the differences of CE and DB = 10.

PROBLEM II.

IN a right-angled \triangle having given the Hypotenuse and sum of the sides, to find the sides. E. g. If the Hypotenuse BC be given (Fig. 32.) and the sum of the sides CAB, to find the sides AB and AC separately, to form the Triangle.

SOLUTION.

Make the Hypotenuse BC = a , the sum of the sides = b . Make one side e. g. AB = x , then will the other side AC be = $b - x$. Therefore

$2xx - 2bx + bb = aa$; and adding $2bx$, and taking away bb , $2xx = 2bx + aa - bb$; and dividing by 2,

$$xx = bx + \frac{aa - bb}{2}$$

Therefore according to Case 1. of affected Quadratics,

$$x = \frac{1}{2}b + \sqrt{\frac{1}{4}bb + \frac{aa - bb}{2}}$$

$$\text{i. e. } \frac{1}{2}b + \sqrt{\frac{1}{4}aa - \frac{1}{4}bb}$$

$$\text{or } \frac{1}{2}b - \sqrt{\frac{1}{4}aa - \frac{1}{4}bb}.$$

The Geometrical Construction. Having described a semi-circle upon BD = BC so a apply therein the equal lines BE and DE, and having described another semi-circle on BE apply therein BF = $\frac{1}{2}b$, to be prolonged farther out. Lastly, if another little semi-circle be described at the interval EF, the whole line AB will

will be the true root or the side sought, and GB the false root, &c.

The Arithmetical Rule. From half the square of the Hypothenusa subtract the fourth part of the square of the given sum, and the root extracted out of the remainder, if it be added to half the sum, will give one side of the Triangle; and subtracted from the given sum, will give also the other. Suppose *e. g.* BC to be 20, and the sum of the sides 28.

PROBLEM III.

Having given again in the same Δ the Hypothenusa, as above, and the difference of the sides DB (Fig. 33.) to find the sides.

SOLUTION.

Make the less side x , the difference of the sides $= b$; the greater side will be $x + b$. Let the Hypothenusa be $= a$.

Therefore, $2xx + 2bx + bb = aa$; and taking away $2bx + bb$,

$$2xx = aa - 2bx - bb; \text{ and dividing by } 2,$$

$$xx = \frac{aa - 2bx - bb}{2}$$

$$\text{Therefore by case 2, } x = \frac{-\frac{1}{2}b + \sqrt{\frac{1}{4}bb + aa - \frac{1}{4}bb}}{2}$$

$$\text{i. e. } \frac{-\frac{1}{2}b + \sqrt{\frac{1}{2}aa - \frac{1}{4}bb}}{2}$$

The Geometrical Construction. Having described a semi-circle upon BD $=$ BC or a , apply therein the equal lines BC and DC, and having described another semi circle on DC apply in it DF $= \frac{1}{2}b$, and if at the same interval you cut off FA from FC, the remainder AC will be the lesser side sought, &c.

The Arithmetical Rule. From half the square of the Hypothenusa subtract the square of half the difference, and if you take half the difference from the root extracted out of the remainder, you'll have the lesser side of the Triangle required, and by adding to it the given difference you'll have also the greater. *E. g.* Let the Hypothenusa be 20, and the difference of the sides 4.

PRO-

PROBLEM IV.

HAVING given the Area of a right-angled Parallelogram, and the difference of the sides to find the sides. E. g. If the Area is \equiv to the square of the given line DF, and the difference of the sides ED (Fig. 34.) to find the sides of the rectangle.

SOLUTION.

Make the given Area $\equiv aa$, the difference of the sides $\equiv b$, the lesser side x ; then the greater will be $x + b$. Therefore the Area $xx + bx \equiv aa$; and subtracting bx
 $xx \equiv \text{---} bx + aa.$

Therefore according to case 2, $x \equiv \text{---} \frac{1}{2}b + \sqrt{\frac{1}{4}bb + aa}.$

The Geometrical Construction. Join at right angles AG $\equiv a$, and GH $\equiv \frac{1}{2}b$, and having drawn AH and prolong'd it, describe the little Circle at the interval GH: so you'll have AE the lesser side, and AD the greater of the Rectangle sought, &c.

The Arithmetical Rule. Add the given Area and the square of half the difference, and having the sum, subtract and add the difference from or to the root extracted, and so you'll have the greater and less sides of the rectangle.

PROBLEM V.

HAVING given for a right-angled Triangle the difference of both the Legs from the Hypotenusa, to find the sides and so the whole Triangle. E. g. Suppose the difference of the less side to be BD and of the greater DE (n. 1. Fig. 35.) to find the sides themselves, and so make the Triangle.

SOLUTION.

For BD put a , for DE, b . Let the greater side be x ; the Hypotenusa will be $x + b$; therefore the lesser side will be $x + b - a$. Now the $\square \square$ of the sides are \equiv to the \square of the Hypotenusa, i. e. $2xx - 2ax + 2bx + bb - 2ab + aa \equiv xx$

$= xx + 2bx + bb$; and taking away $xx + 2bx + bb$,
 $xx - 2ax - 2ab + aa = 0$; and adding $2ax$ and
 $2ab$, and taking away aa ,

$xx = 2ax + 2ab - aa$. Therefore

$$x = a + \sqrt{aa + 2ab - aa}; \text{ i. e.}$$

$$x = a + \sqrt{2ab}.$$

The Geometrical Construction. Between the given differences BD and DE. find (*n* 2.) a mean proportional DF, and join to it at right angles the equal line FG, and cut off DH equal to DG; and so you'll have BH the greater side of the triangle sought. This being prolong'd to C, so that HC shall be $= b$, having described a semi-circle upon the whole line BC apply therein BA $=$ BH; and having drawn AC, the Triangle sought ABC, will be formed.

The Arithmetical Rule. If the square root extracted from the double rectangle of the differences be added to the greater difference, you'll have the greater side sought, &c.

PROBLEM VI.

HAVING given, to make two unequal Rectangles, but of equal height, the sum of their Bases with the Area of either (*viz.* the greater,) and the proportion of the sides of the other (*viz.* the least,) to find the sides separately. E. g. Let the sum of the bases be AB (*n*. 1. Fig. 36) and the square of the line BC $=$ to the Area of the greater rectangle; and let the sides of the lesser rectangle be to one another as CD to DE: To find the sides of both the rectangles; *i. e.* to find the common altitude, which being found the other sides will be easily obtain'd from the *Data*; or to find the base of the greater which, with the same ease, will discover the rest.

SOLUTION.

Make AB $= a$, and the Area of the greater rectangle $= bb$; and the proportion of the altitude to the base in the lesser, as *c* to *d*; to find *e. g.* the greater base which call *x*. Therefore the common altitude will be $= \frac{bb}{x}$, and the base of the lesser

$$\text{triangle} = a - x.$$

G g

Where-

Wherefore you'll have for the Equation,
as c to d so $\frac{bb}{x}$ to $a - x$.

Therefore $ac - \frac{cx}{x} = \frac{bbd}{x}$; and multipl. by x ,

$acx - cxx = bbd$; and adding cx and taking away bbd ,

$acx - bbd = cxx$. Now that you may conveniently divide both sides by c , make first as c to b so d to a fourth which call f , and then put cf for bd , and you'll have

$acx - bcf = cxx$; and dividing by c

$ax - bf = xx$; and so according to case 3.

$$x = \frac{1}{2}a \pm \sqrt{\frac{1}{4}aa - bf}$$

$$\text{or } \frac{1}{2}a - \sqrt{\frac{1}{4}aa - bf}.$$

The Geometrical Construction. Find first the quantity f (num. 2. Fig. 36.) according to the following proportion, as c to b so d to f ; and a mean proportional between b and f will be $= \sqrt{bf}$. Then having at the interval $\frac{1}{2}a$ described a semi circle (n. 3.) upon the given line AB , and erected $BD = \sqrt{bf}$, and having made $EF =$ to it, CF will be $\sqrt{\frac{1}{4}aa - bf}$. To which AC being added will give x for one value and FB for the other. And for the common altitude, which we called $\frac{bb}{x}$, make as x to b , so b to a fourth, i. e. as AF to FH so

FH to FG ; which will be the altitude of both rectangles Ag and Bg which may now easily be constructed.

The Arithmetical Rule might easily be had from this Equation reduced; but you may have it more commodiously from this other

SOLUTION.

Let the Denomination remain the same as above, only here put x for the common altitude, and express the reason of the lesser base of the rectangle to this altitude by e , and that base will be $= ex$: Therefore the base of the greater Rectangle will be $= a - ex$. Having now multiplied the common altitude by each base, the area of the greater rectangle will be $ax - exx$, and hence you'll have the Equation

$ax - exx = bb$; and adding exx , and taking away
 $ax - bb = exx$; and dividing by e ,
 $\frac{ax - bb}{e} = xx$. Therefore by case 3.

$$x = \frac{a}{2e} + \sqrt{\frac{aa - bb}{4ee}} \text{ or } x = \frac{a}{2e} - \sqrt{\frac{aa - bb}{4ee}}$$

Wherefore now this will be the *Arithmetical Rule*. If from the fourth part of the square of the sum of the bases divided by the \square of the name of the reason you subtract the given area divided by the same name of the reason, and if the root extracted out of the remainder be added to or subtracted from half the sum of the bases divided by the same name of the reason; this sum or remainder will give the altitude of the given Rectangles, and that multiplied by the name of the reason one of the bases: and that being subtracted from the given sum of the bases will give the other base. For Example, let the sum of the bases be 16, the area of one of the rectangles 30, the name of the reason which the common altitude has to the base of the other rectangle = 2. There will come out the common altitude, on the one side 5, on the other 3, &c.

PROBLEM VII.

Having given the Perpendicular of a right-angled Triangle let fall from the right angle, and its Base, to find the segments of the Base, and so to form the Triangle.

E g. If the base of the right-angled Triangle you are to form be AB (Fig. 37.) and the length of the perpendicular be BF; to find the segments of the base, and so the point from which you are to make the perpendicular CD, to form the Triangle ABG.

SOLUTION.

Let the given base be = a ; and the given perpendicular be b : Then will one of the segments of the base be = x ; and the other = $a - x$, and b a mean proportional between the said segments, i. e.

$$x \text{ to } b \text{ as } b \text{ to } a - x;$$

Therefore $ax - xx = bb$; and by adding xx and taking away bb ,

G g 2

 $ax -$

$ax - bb = xx$. Therefore by case 3.

$$x = \frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$$

$$\text{or } \frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}.$$

The Geometrical Construction. Having described a semi-circle upon the given line AB, if you erect the perpendicular BE, and from the point G (which is determined by EG parallel to AB) let fall GD equal to it, you will have the two segments sought, $AD = \frac{1}{2}a + \sqrt{\frac{1}{4}aa - bb}$ and $DB = \frac{1}{2}a - \sqrt{\frac{1}{4}aa - bb}$, which Construction, it cannot be denyed, but it may be evident to any attentive person even without the Analysis.

But that case may by the by be taken notice of wherein the given perpendicular would not be BE but BF. For in this case the perpendicular BF being erected upon AB, the parallel FG would not cut the semi-circle; which is an infallible sign that the Problem in this case is impossible, where the perpendicular is supposed to be greater than half the base; which is inconsistent with a right angle.

The Arithmetical Rule. From the square of half the base take the square of the given perpendicular, and add or subtract the square root extracted out of the remainder, to or from half the base; and on the one hand the sum will give the greater segment, and on the other the difference will give the less.

PROBLEM VIII.

HAVING given the perpendicular of a right-angled Triangle that is to be let fall from the right angle, and the difference of the segments of the base, to find the segments, and describe the Triangle.

E. g. If the perpendicular is, as above, BE, and the difference of the segments AH (*n. 1. Fig. 38.*) to find the segments AD and DB, from whose common term you are to erect a perpendicular DG or DC to form the Triangle.

S O L U T I O N.

Make the lesser segment $\equiv x$, and the difference of the segments $\equiv a$, the greater segment will be $x + a$. Make the given perpendicular as before $\equiv b$: Therefore you'll have as $x + a$ to b so b to x ; and consequently,
 $xx + ax \equiv bb$; and subtracting ax ,
 $xx \equiv bb - ax$. Wherefore according to case 2.

$$x \equiv -\frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}.$$

The Geometrical Construction. Make $HD \equiv \frac{1}{2}a$, DG equal and perpendicular to b ; HG will be $\equiv \sqrt{\frac{1}{4}aa + bb} \equiv HB$ or A , viz. having drawn a semi-circle from H thro' G . Therefore DB is the less segment, and AD the greater; and having drawn AG and BG , or on the other side, (making the perpendicular $DC \equiv DG$) having drawn AC and BC , the triangle will be constructed. Or with *Cartes*, make (*n. 2.*) $AE \equiv \frac{1}{2}a$ and $EB \equiv b$, and having described a Circle from thro' E draw BHA ; and so you'll have the two segments sought AB the greater and DB the lesser.

The Arithmetical Rule. Join the squares of the half difference and perpendicular into one sum, and then having extracted the root subtract half the difference from it; and the remainder will be the lesser segment sought; and having added the difference you'll have also the greater.

P R O B L E M IX.

HAVING given for a right-angled Triangle one segment of the base and the side adjacent to the other segment, to find the rest and construct the Triangle.

As if the lesser segment of the base DB be given (*Fig. 39.* 1.) and the side AC adjacent to the other segment; to find the greater segment of the base, which being found the rest easily obtain'd, and consequently the whole Triangle.

S O L U -

S O L U T I O N.

Make the greater segment $= b$, the given side $= c$, the segment sought $= x$. Now if we suppose the triangle ABC to be already found, it is evident, 1. If from the square of AC you subtract the \square AD, you'll have the \square CD $= cc - xx$. 2. The same \square CD may also be otherwise hence obtain'd, because, the angle at C being a right one, CD is a mean proportional between BD and DA, *i. e.* between b and x ; whence the rectangle of the extremes bx is $= \square$ of the mean CD. Wherefore now it follows, 3. that

$$cc - xx = bx; \text{ and adding } xx,$$

$$cc = bx + xx; \text{ and subtracting } bx,$$

$$-bx + cc = xx. \text{ Therefore according to case 2.}$$

$$x = -\frac{1}{2}b + \sqrt{\frac{1}{4}bb + cc}.$$

Geometrical Construction. Join $EF = \frac{1}{2}b$ (*n. 2. Fig. 39.*) and $FA = c$ at right angles, and having described a Circle from E thro' F draw AEB; so you'll have DA the greater segment and DB the less; having erected therefore a perpendicular from D, and described a semi-circle upon AB, you'll have C the vertex of the triangle sought, whence you are to draw the sides AC and BC.

The Arithmetical Rule. Join the \square of half the given segment, and the \square of the given side into one sum; and having extracted the root of it, if you thence take half the given segment, you'll have the segment sought.

P R O B L E M X.

HAVING given in an oblique angled Triangle the perpendicular height, and the difference of the segments of the base, and the difference of the other sides, to find the sides and form the triangle.

As, if the altitude CD be given (*n. 1. Fig. 40.*) and also the difference of the segments of the base EB, and the difference of the sides FB (as is evident from the triangle ABC (*n. 2.*) conceived to be so formed beforehand) and you are to determine the base it self and both sides, &c.

S O L U.

S O L U T I O N.

Make the given perpendicular $CD = a$ (see n. 2. Fig 40.)
 $EB = b$, $FB = c$: For the lesser segment of the base AD put
 x , and the greater will be $x + b$. It is now evident that you
 may obtain the $\square CB$ by the addition of the $\square DC$ and BD ,
 $ac + xx + 2bx + bb$; and the $\square AC$ by the addition of the
 $\square AD$ and DC , viz. $aa + xx$: So that the side AC will
 be $= \sqrt{aa + xx}$, and the side $BC = \sqrt{aa + xx + 2bx + bb}$.
 But since also this same side BC may be obtain'd by adding
 the difference c to the side AC , so that it shall be $= c + \sqrt{aa + xx}$:
 you'll have this Equation,

$c + \sqrt{aa + xx} = \sqrt{aa + xx + 2bx + bb}$; and squaring
 both sides,

$$cc + aa + xx + \sqrt{4ccaa + 4ccxx} = aa + xx + 2bx + bb;$$

and subtracting from both sides $cc + aa + xx$,

$$\sqrt{4ccaa + 4ccxx} = 2bx + bb - cc;$$

and again squaring it,

$$4ccaa + 4ccxx = 4bbxx + 4b^3x - 4bcx + b^4 - 2bbcc + c^4;$$

and subtracting from both sides $4ccxx$ (because c is less than b)

and transposing the rest,

$$4ccaa - 4b^3x - b^4 + 4bccx + 2bbcc = 4bbxx - 4ccxx;$$

and dividing by $4bb - 4cc$,

$$4ccaa - 4b^3x - b^4 + 4bccx + 2bbcc = xx.$$

i. e. dividing the affected quantities by 4 both above and un-
 derneath,

$$\frac{-b^3x + 4ccaa - b^4 + 2bbcc - c^4}{4bb - 4cc} = xx$$

and actually dividing the former part by $bb - cc$

$$\frac{-bx + 4ccaa - b^4 + 2bbcc - c^4}{4bb - 4cc} = xx,$$

Therefore

Therefore according to the second case,

$$\sqrt{\frac{1}{2}b + \sqrt{\frac{1}{4}bb + \frac{4ccaa}{4bb - 4cc} - b^4 + 2bbcc - b^4}} = x;$$

or reducing $\frac{1}{4}bb$ to the same denomination with the rest

$$\sqrt{\frac{1}{2}b + \sqrt{\frac{bb^2 + 4ccaa - b^4 + 2bbcc - c^4}{4bb - cc}}} = x;$$

and leaving out those quantities that destroy one another

$$\sqrt{\frac{1}{2}b + \sqrt{\frac{4ccaa + bbcc - c^4}{4bb - cc}}} = x.$$

The Arithmetical Rule. Multiply four times the square of FB by the square of the perpendicular CD, and add to it the product of the square of EB into the \square FB, and from the sum subtract the biquadrate of FB; and the remainder will be the first thing found. Then subtract four times the square of FB from four times the square of EB; and the remainder will be the second thing found. Lastly, divide the first thing found by the second, and from the quotient take half after having extracted the root: Thus you'll have the lesser segment of the base sought, &c. E. g. In numbers you may put 2 for FB, 4 for EB, 12 for CD.

As for the *Geometrical Construction*, the quantity of the last Equation contain'd under the radical sign will help us to this proportion,

as $4bb - 4cc$ to $4aa + bb - cc$ so cc to a fourth; or dividing all by 4,

as $bb - cc$ to $aa + \frac{1}{4}bb - \frac{1}{4}cc$; so $\frac{1}{4}cc$ to a fourth, which is $\frac{1}{4}$ of the quantity under the radical sign. Assuming therefore the quantity c for unity, make (*n. 3.*) $IK = c$ IN and $KL = b$; NO will be $= bb$, and subtracting $OP = cc$ (*i. e.* to unity) there will remain $NP = bb - cc$. In like manner IS and $KM = a$, ST will $= aa$; to which if you add $SX = \frac{1}{4}NO$, and take thence $XV = \frac{1}{4}$ unity; TV will be $= aa + \frac{1}{4}bb - \frac{1}{4}cc$. Wherefore if you make NR equal to this TV , and $PQ = \frac{1}{4}$ of unity or cc , since NP is $= bb - cc$; by the rule of proportion there will come out DR $\frac{1}{4}$ of that quantity, which is under the radical sign. Therefore this being taken four times will give DZ for the whole quantity; to which if you

you join $Dy \equiv$ to unity, and, having described a semi-circle upon the whole line YZ , erect the perpendicular DE ; this will be the root of the said quantity, and taking hence moreover $EF \equiv \frac{1}{2}b$, you'll have DE or DA the less segment of the base sought. Therefore adding $GB \equiv b$ to DG , DB will be the greater segment, and, having let fall the perpendicular $DC \equiv a$, BC and AC will be the sides sought. Q. E. F.

IV. *Some Examples of Affected Biquadratick Equations, but like Affected Quadratick ones.*

PROBLEM I.

TO find a square $ABCD$ (such as in the mean while we'll suppose $n. 1.$ to be in Fig. 41.) from which having taken away another square $AEFG$, which shall be half the former, there will be left the Rectangle GC whose Area is given. E. g. suppose the given area equal to the square of the given line LM , to find the true sides of the squares AB and AE , answering to these supposed ones, $n. 1.$

SOLUTION.

Make the area of the rectangle that is to remain $\equiv bb$, and $GB \equiv x$; BC or AB will be $\equiv \frac{bb}{x}$, and subtracting hence

GB , the remaining side of the lesser square $AG \equiv \frac{bb}{x} - x$;

$\frac{bb}{x} - xx$. Since therefore the square of this is supposed

to be half of the square of AB , this will be the Equation :

$$\frac{b^4 - 2bbxx + x^4}{xx} = \frac{b^4}{2xx};$$

and multiplying by xx ,

$$b^4 - 2bbxx + x^4 = \frac{b^4}{2}$$

and multiplying by 2,

$$2b^4 - 4bbxx + 2x^4 = b^4;$$

Hh

and

and subtracting $2b^4$, and adding $4bbxx$;

$$2x^4 = 4bbxx - b^4;$$

and dividing by 2,

$$x^4 = 2bbxx - \frac{b^4}{2}.$$

NB. The same Equation may be obtain'd, if, putting x for GB or FH, and having found the \square of AG or GF as above, you infer

$$\frac{b^4 - 2bbxx + x^4}{xx} = 2bb - xx.$$

This last Equation, tho' it be a biquadratick, yet may be rightly esteem'd only a quadratick one, because there is neither x^3 nor single x in it, and so you may substitute this for it,

$$yy = 2bby - \frac{b^4}{2}, \text{ viz. by supposing } y = xx. \text{ Whence}$$

according to the third case of affected quadraticks,

$$y \text{ will } = bb + \sqrt{\frac{b^4}{2} - \frac{b^4}{2}} \text{ i. e. } \sqrt{\frac{b^4}{2}}$$

$$\text{or } = bb - \sqrt{\frac{b^4}{2}}$$

$$\text{Therefore } x = \sqrt{bb + \frac{\sqrt{b^4}}{2}}$$

Geometrical Construction. Now if the given line b be assumed for unity, bb and b^4 will be $=$ to the same line. Therefore, if between LM as unity, and MN $= \frac{1}{2}b$ viz b^4

you find a mean proportional MO (*n. 2. Fig. 41.*) that will be $= \sqrt{\frac{b^4}{2}}$, which being subtracted from LM, and added to

it, will give the two values of the quantity y . Moreover therefore by extracting its roots, *i. e.* by finding other mean proportionals LR and LS between the quantities found LP and LQ and unity (*n. 3.*) they will be the two values of the quantity x sought; the first whereof LR will satisfy the question, and the other LS be impossible. Wherefore to form the

the square it self, since its side will be $\equiv \frac{bb}{x}$; by making (*n* 4.)

as *x* to *b* so *b* to a fourth, it will be obtain'd: And this may be further prov'd, if finding a mean proportional BK between BI \equiv LR and the side of the \square BC, it be equal to the given quantity LM.

Arithmetical Rule. From the given area or the square of the given line LM subtract the root of half the biquadrate of the same line; thus you will have the value of the \square FC, *xx*: Therefore extracting further the square root of this, it will be the value of *x* sought.

PROBLEM II.

To find another square ABCD (Fig. 42. n. 1.) out of the middle whereof if you take another square EFGH, which shall be a fourth part of the former, the area of the rectangle intercepted between BC and FG prolonged, shall be equal to the square of a given line LM; i. e. having these given to find the segment BI, and consequently also the side BC or

SOLUTION.

Make the area of the given rectangle, or the square of LM to *bb*, and the side sought of the rectangle BI $\equiv x$; the other side BC will be $\equiv \frac{bb}{x}$, and having subtracted out of it

and GK (*i. e.* *2x*) the side of the lesser square FG will be $\frac{bb}{x} - 2x$, i. e. $\frac{bb - 2xx}{x}$; whose square since it is the

fourth part of the greater square by the Hypothesis, you'll have

$$\frac{bb^2 - 16bbxx + 4x^4}{xx} = \frac{b^4}{xx};$$

multiplying both sides by *xx*,

$$bb^2 - 16bbxx + 4x^4 = b^4;$$

taking away $4b^4$, and adding $16bbxx$,

$$4x^4 = 16bbxx - 3b^4;$$

H h 2

and

and dividing by 4,

$$x^4 = 4bbxx - \frac{3}{4}b^4.$$

Therefore according to the third case of affected quadratick Equations,

$$xx = 2bb \pm \sqrt{4b^4 - \frac{3}{4}b^4} \text{ i. e.}$$

$$= 2bb \pm \sqrt{3\frac{1}{4}b^4}.$$

$$\text{Therefore } x = \sqrt{2bb} \pm \sqrt{3\frac{1}{4}b^4}.$$

Geometrical Construction. If the given line b be taken for unity, b^4 and bb will be equal to it. Therefore if between LM as unity, and MN = $3\frac{1}{4}b$, you find a mean proportional MO (*n. 2. Fig. 42.*) 'twill be $\sqrt{3\frac{1}{4}b^4}$; which subtracted from MQ = $2b$, or added to it, will give two values of the quantity xx , viz. PQ and IQ; the first whereof will be only a true one, and of use here. Now therefore a mean proportional QR found between PQ and unity will express the quantity sought x .

Therefore for forming the square it self, since its side AB is = $\frac{bb}{x}$, you may proceed as in the former Construction, (*vide*

n. 3.)

PROBLEM III.

Having given the base of a right-angled Triangle, and a mean proportional between the Hypotenuse and Perpendicular, to find the Triangle. As if the given base be AB (*Fig. 43.*) and the mean proportional between AC and BC be CD; to find the perpendicular BC, and Hypotenuse AC.

SOLUTION.

Make the given base = a , and the mean proportional = the perpendicular BC = x , then will the Hypotenuse be the Hypoth., — $\frac{bb}{x}$.

Theref

XLIII

XLIV

XLIV

Therefore

$$b^4 - aa + xx;$$

xx

and multiplying both sides by xx ;

$$b^4 = aaxx + x^4;$$

and subtracting $aaxx$,

$$b^4 - aaxx = x^4.$$

Therefore by the second case of affected quadratics

$$xx = -\frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + b^4},$$

$$\text{and } x = \sqrt{-\frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + b^4}}.$$

Or thus.

Make the Hypotenuse $AC = x$, then will the perpendicular be $BC = \frac{bb}{x}$. Therefore

$$xx = aa + \frac{b^4}{xx};$$

and multiplying by xx ,

$$x^4 = aaxx + b^4.$$

Therefore by case 1.

$$xx = \frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + b^4}$$

$$\text{and } x = \sqrt{\frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + b^4}}.$$

Geometrical Construction; the first for the latter Equation. Let a be put for unity, the line AB will be also $= aa$, and taking, as a to b so b to a third, *i. e.* as LM to MN so LO to OP , and you'll have bb . Having erected the perpendicular $AQ = OP$ upon AM , and drawn MQ or Mn equal to $\sqrt{\frac{1}{4}a^4 + b^4}$, and consequently An will be $= \frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + b^4}$, *i. e.* the value of xx . Moreover a mean proportional AC found between An and AR unity will be the value of x , *i. e.* the Hypotenuse sought; which being found, you may easily complete the Triangle ABC .

2. In the case of the former Equation, making every thing before AK would be the value of the quantity xx , *i. e.*

$$-\frac{1}{2}a + \sqrt{\frac{1}{4}a^4 + b^4}.$$

Therefore a mean proportional RT found between $RS = AK$ and AR unity will be the value of x , *i. e.* the

i. e. the perpendicular sought, and so AT the Hypotenusa of the Triangle sought.

Arithmetical Rule. In the first Solution add the biquadrate of the given mean proportional to the biquadrate of half the given base; and having extracted the square root of the sum, take from it half the square of the given base; the root of the remainder will give the perpendicular of the triangle sought, and the root of the sum will give the hypotenusa of it.

PROBLEM IV.

HAVING the Hypotenusa of a right-angled Triangle given, and a mean proportional between the sides to find the Triangle. As if the hypotenusa be AC (Fig. 44.) and a mean proportional between the sides BD, to find the sides AB and BC.

SOLUTION.

Make the given Hypotenusa $\equiv a$, and the mean proportional $\equiv b$, and the perpendicular BC $\equiv x$; the basis AB by the hypoth. will be $\frac{bb}{x}$. Therefore

$$\frac{b^4}{xx} + xx \equiv a;$$

and multiplying by xx ,

$$b^4 + x^4 \equiv aaxx;$$

and subtracting b^4 ,

$$x^4 \equiv aaxx - b^4;$$

Therefore by the third case,

$$xx \equiv \frac{1}{2}aa \pm \sqrt{\frac{1}{4}a^4 - b^4}$$

$$\text{and } x \equiv \sqrt{\frac{1}{2}aa \pm \sqrt{\frac{1}{4}a^4 - b^4}}.$$

Geometrical Construction. If a be put for unity, AC will be also $\equiv aa$, and by making as AC to CG (a to b) so AF to GH (b to a third) this third will be GH $\equiv bb$. Assuming therefore OC $\equiv \frac{1}{2}aa \equiv$ OB the radius of a semi-circle, and having erected CD $\equiv bb \equiv$ BE parallel to it, EO will be $\sqrt{\frac{1}{2}aa \pm \sqrt{\frac{1}{4}a^4 - b^4}}$

$\sqrt{\frac{1}{4}a^2 - b^2}$, and consequently $EC = \frac{1}{2}a - \sqrt{\frac{1}{4}a^2 - b^2}$, and $EA = \frac{1}{2}a + \sqrt{\frac{1}{4}a^2 - b^2}$, viz. the double value of the quantity xx . Therefore for the double value of x , you must extract the roots out of them, i. e. you must find the mean proportionals AL and AM between unity AC and AI = EC on the one side, and AK = AE on the other; Altho' these last may be more compendiously had, and the triangle it self immediately constructed, if having found EC and EA, you draw CB and AB: For these will be those two last mean proportionals = AL and AM; for by reason of the $\triangle ABC$, AEB, and BEC, BC is a mean proportional between AC and CE, and AB a mean proportional between the same AC and AE by the 8. Lib. 6. Eucl. which is Consect. 3. Schol. 2. Prop. 34. Lib. 1. Math. Enuci.

PROBLEM V.

HAVING given the Area and Diagonal of a right-angled Parallelogram, to find the sides and so the Parallelogram. As if the given Area be = to the square of a given line BD (Fig. 45.) and the Diagonal AC, to find the sides AB and BC.

SOLUTION.

If for the given Area, or square of the line BD you put bb , and make the Diagonal AC = a , and put for the lesser side BC, x ; the other side will be $\frac{bb}{x}$.

Therefore $\frac{b^4}{xx} + xx = aa$;

and multiplying by xx ,

$b^4 + x^4 = aaxx$; and subtracting b^4 ,
 $x^4 = aaxx - b^4$. Which Equation, since it is the same with that of the preceding Problem (which is no wonder, since this fifth perfectly coincides with the fourth; for the Diagonal AC is the hypotenuse, and BD, whose square is = to the given area of the rectangle, is a mean proportional between the sides AB and BC) and so will have the same Construction,

struction, (see Fig. 45.) and the same Arithmetical Rule, which may be easily formed from the last Equation of the preceding Problem.

PROBLEM VI.

HAVING given the first of three proportional lines, and another whose square is equal to both the squares of the other two, to find those two proportionals. As if AC (Fig. 46.) be the first of the three proportionals, and another line ED given, whose square equals the two squares of the others taken together; to find those two as second and third proportionals.

SOLUTION.

If for AC you put a , and make the given line $ED = c$, and the second proportional $= x$, the third will be $\frac{xx}{a}$. Where-

fore the squares of the two last will be $\frac{x^4}{aa} + xx = cc$, $\square ED$

by the hypoth. and multiplying both sides by aa .

$$x^4 + aaxx = aacc;$$

and subtracting $aaxx$,

$$x^4 = \frac{aaxx + aacc}{aa} \quad \text{Therefore}$$

$$xx = \frac{\frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + aacc}}{aa}$$

$$\text{and } x = \sqrt{\frac{1}{2}aa + \sqrt{\frac{1}{4}a^4 + aacc}}.$$

Geometrical Construction. If a be put for unity, AC will also $= aa$ and a^2 , and making as AC to CD (a to c) so AF to DE (c to a third) DE will be $= cc$. Now having made AK $= DE$, i. e. cc , a mean proportional AI found between AC and AK will be \sqrt{aacc} . Therefore taking $AO = \frac{1}{2}AC$, viz. $\frac{1}{2}aa$, the hypotenuse OI will be $= \sqrt{\frac{1}{4}a^4 + aacc}$. And OA $= \frac{1}{2}a$ being subtracted from OI or OH equal to it will leave AH the value of xx ; and the root of that being extracted, i. e. finding another mean proportional AG between AC and AH, it will be the value of x , i. e. the second of the proportionals sought, and since AC is the first given, AH will be the third. Q. E. F.

NB. This

NB. This Construction may be abbreviated, and the first Operation, by which you find DE, to which afterwards AK is made equal, may be omitted. For since you make use of a mean proportional between CA and DE sought, which is $\frac{1}{2}$ to the given line ED, and afterwards AI a mean proportional between AC and AK is sought; it is evident that AI will be equal to ED given, and consequently that they may be immediately joined at right angles at the beginning of the given line AC, and the rest may then be done as before.

Some Examples of Cubick and Biquadratick Equations, both simple and affected, whether reducible or not.

PROBLEM I.

Between two given right angles to find two mean proportionals. E. g. Suppose given AB the first and CD the fourth, (Fig. 47. n. 1.) between these to find two mean proportionals.

SOLUTION.

Make the first of the given quantities $AB = a$, the other $CD = q$, the first mean $= x$, then will the latter be $\frac{xx}{a}$, and consequently $\frac{x^3}{aa} = q$; and multiplying by aa , $x^3 = aaq$.

The Central Rule will b $\frac{L}{2} = AD$

$$\frac{r}{2}$$

$2L^2 = DH$. i. e. according to a supposition we shall by and by make, $\frac{1}{2}a = AD$, and $\frac{1}{2}q = DH$.

Geometrical Construction. If AB or a be made unity, and also the *Latus Rectum* of your Parabola, and you describe, by means of this *Latus Rectum*, the Parabola, according to *Schol.*

Prop. 1. Lib. 2. Math. Enucl. [see n. 2. and 3. Fig 47.]

in which AB is the *Latus Rectum*; A1, A2, &c. the Abscissas; AI, AH, &c. the semiordinates; make moreover (*n.*) $AD = \frac{1}{2}a$, and having from D erected a perpendicular $\frac{1}{2}q$, describe a circle at the interval AH, cutting the parabola

l i

bola

bola in N: Which being done, a perpendicular to the Ax will be the root sought or the value of x , i. e. the first of the means, and consequently OA the other; since NO by the first property of the Parabola (see *Prop. 1. Lib. 2. Mathes. Erucl*) is a mean proportional between the *Latus Rectum* AB, and the abscissa AO. And by this means there will come out, by *Baker's Central Rule* the very construction of *Des Cartes*, *Geom.* p. m. 91.

The Arithmetical Rule. Multiply the square of the first by the fourth given, and the cube root extracted out of the product, will express the first of the means sought.

PROBLEM II.

HAVING given the solid Contents of a solid or an hollow Parallelepiped, and the proportion of the sides, to find the sides. As, if the given capacity or solid contents be \equiv to the cube of a certain given line IK (*Fig. 48. n. 1.*) and the proportion of the height to the length be as AB to BC, and to the latitude as the same AB to BD; to find first the altitude, which being had, the other Dimensions will also be known, by the given proportions.

SOLUTION.

Make IK $\equiv a$, AB $\equiv b$, BC $\equiv c$, and BD $\equiv d$; and lastly the height sought $\equiv x$, then

as b to c , so x to the length required $\frac{cx}{b}$;

and as b to d , so x to the latitude sought $\frac{dx}{b}$.

Multiplying therefore these three dimensions of the Parallelepiped together, you'll have its capacity or solid contents $\frac{cdx^3}{bb}$

$\equiv a^3$;

and multiplying by bb ,

$cdx^3 \equiv a^3bb$; and dividing by cd ,

$x^3 \equiv \frac{a^3bb}{cd}$ i. e. $x^3 \equiv \frac{a^3bb}{cd} \equiv 0$.

There-

Therefore the Central Rule will be the same as above,

$$\frac{L}{2} \equiv AD \text{ and } \frac{r}{2L^2} \equiv DH, \text{ i. e. according to the supposi-}$$

tion which will by and by follow,

$$\frac{a}{2} \equiv AD \text{ and } \frac{a^3bb}{2cd} \equiv DH.$$

Geometrical Construction. If IK or a be made unity, and at the same time *Latus Rectum*, and by means of it you describe a Parabola, after the way we have shewn, Fig. 47. n. 2. and 3. and shall always hereafter make use of; and then to prepare the quantity $\frac{a^3bb}{2cd}$ (which in the Central Rule is the

the quantity $\frac{r}{2}$) make (n. 2.)

$$\frac{IK-IM}{2} \equiv BC-KL \equiv BD-MN$$

as a to e so d to e ;

so that for cd you may put ae , and afterwards divide by a both above and underneath; you'll have the quantity $\frac{r}{2} \equiv \frac{aabb}{2e}$.

Therefore by further inferring

as $2e$ to bb , so aa to a fourth

IO—IP \equiv IT—IK—IQ, and you'll have the quantity DH, which will determine the centre, after AD is made equal $\frac{a}{2}$. Having therefore described from that centre

a circle through the vertex of the Parabola A (n. 3.) a semi-ordinate NO drawn from the intersection will be the altitude sought, which will easily give you the length and breadth by the reasons above shewn.

Another Solution.

Which will be more accommodated to the Arithmetical Rule.

Let the rest of our Positions or *Data* remain as above, but the name of the proportion which the altitude has to the length be $\equiv e$, and of that which it has to the latitude $\equiv i$, the

I i 2 length

length will be \equiv to ex , and the latitude to ix . Wherefore multiplying the sides together, you'll have the whole solidity

$eix^3 \equiv a^3$; and dividing by ei ,

$x^3 \equiv \frac{a^3}{ei}$. Therefore

$$x \equiv \sqrt[3]{C. \frac{a^3}{ei}}. \text{ Hence}$$

The Arithmetical Rule. Multiply together the given names of the reasons, and divide the given cube by the product which done, the cubick root extracted out of the quotient will be the altitude of the solid sought.

Another *Geometrical Construction*. Now if we would also construct this Equation $x^3 \equiv \frac{a^3}{ei}$ geometrically, putting $AB \equiv$

for unity, BC and BD will be the names of the reasons \equiv and i . Making therefore first

$IK \text{---} IM \text{---} KL \text{---} MN$

as a to e so i to a fourth f (*Fig. 49. n. 1.*) af will be $\equiv ei$, and the proposed Equation will have this form:

$$x^3 \equiv \frac{a^3}{af} \text{ i. e. } \frac{aa}{f}$$

Therefore 2. making

as f to a so a to a third IQ , that will be the value of x . But hence 3. by extracting the cube root, i. e. by finding two mean proportionals between unity b , viz. AB and the line found IQ ; the first of them will give the root sought.

NB. The same Central Rule would come out according to *Baker's Central Rule*, which would have the same form of the Equation, as the precedent Example $x^3 \text{---} aa \equiv 0$, i.

$$\text{taking } b \text{ for the Lat. } \begin{cases} \frac{L}{2} \equiv AD \text{ and } \frac{r}{2L^2} \equiv DH, \\ \text{Rect. and unity, } \frac{b}{2} \equiv AD \text{ and } \frac{aa}{2f} \text{ i. e. } \frac{1}{2} IQ \equiv DH. \end{cases}$$

(see *Fig. 49. n. 2.*)

LIII

LII

n.1.

n.3.

n.3.

n.4.

XLIX

PROBLEM III.

Having given the solid contents of a solid or hollow Paralelepiped, and the difference of the sides, to find the sides. If the given capacity be equal to the cube of any given LM (Fig. 50. n. 1.) and the difference whereby the length exceeds the breadth \equiv NO, and the difference by which the breadth exceeds the altitude or depth \equiv PQ, to find the length, breadth and depth.

SOLUTION.

Make the side of the given cube $\equiv a$, the excess of the length above the breadth NO $\equiv b$, and of the breadth above the depth PQ $\equiv c$, make the depth $\equiv x$, the breadth $\equiv x + c$, and the length $\equiv x + b + c$. Multiplying therefore these three dimensions together.

$$\begin{array}{r}
 \text{Length } x + b + c \\
 \text{Breadth } x + c \\
 \hline
 xx + bx + cx \\
 \quad cx + cb + cc \\
 \hline
 xx + 2cx + bx + cb + cc \\
 \text{Depth } x \\
 \hline
 x^3 + 2cx + b \quad x + cb \quad x = a^3 \\
 \quad + b \quad \quad + cc
 \end{array}$$

according to the forms of Baker and Cartes

$$\begin{array}{r}
 x^3 + b \\
 + 2c \quad xx + bc \\
 \quad + cc \quad x - a^3 = 0.
 \end{array}$$

Wherefore the Central Rule contracted by the supposition which will hereafter follow will be this,

$$\frac{L}{2} + \frac{p^2}{8} \simeq \frac{q}{2} = AD$$

$$\text{and } \frac{p}{4} + \frac{p^3}{16} \simeq \frac{pq}{4} \simeq r = DH.$$

e. by virtue of the supposition just now mentioned (which takes LM viz. a for unity and also for Lat. Rectum)

$a +$

$$\frac{a}{2} + \frac{bb}{8} + \frac{4bc}{8} + \frac{4cc}{8} \propto \frac{bc}{2} \propto \frac{cc}{2} = AD. \text{ And}$$

$$\frac{b}{4} + \frac{2c}{16} + \frac{b^3}{16} + \frac{6bbc}{16} + \frac{12bcc}{16} + \frac{8c^3}{16} \propto \frac{bbc}{4} \propto \frac{3bcc}{4} \propto \frac{2c^3}{4}$$

$$\left(\propto \frac{a^3}{2} = DH. \right)$$

Or more short ;

$$\frac{a}{2} + \frac{bb}{8} + \frac{bc}{2} + \frac{cc}{2} - \frac{bc}{2} - \frac{cc}{2} \text{ i. e. } \frac{a}{2} + \frac{bb}{8} = AD; \text{ and}$$

$$\frac{b}{4} + \frac{2c}{16} + \frac{b^3}{16} + \frac{6bbc}{16} + \frac{12bcc}{16} + \frac{8c^3}{16} - \frac{bbc}{4} - \frac{3bcc}{4} - \frac{2c^3}{4}$$

$$\left(\propto \frac{a^3}{2} \text{ i. e. } \right)$$

$$\frac{b}{4} + \frac{2c}{16} + \frac{b^3}{16} + \frac{bbc}{8} \propto \frac{a^3}{2} = DH.$$

Geometrical Construction. If LM or a be taken for unity or *Latus Rectum* of the Parabola to be described, that being described (*Fig. 50. n. 3.*) you are first of all to determine two quantities AD and DH ; which may be done two ways ; either by *Baker's* form of his Central Rule, or by ours immediately divided by the quantities of the last Equation.

1. For AD by our form, $\frac{a}{2} + \frac{bb}{8} = AD$, you must make

(*Fig. 50. n. 1.*) as a to b so b to a third (AB to AC so BE to CF) which will be bb , and D^2 the eighth part of this CF must be added to A^2 the half of AB. And by *Baker's* form you must make, 1. as AB ($= a$, *n. 2.*) to AC ($= \frac{1}{2}p$ i. e. $\frac{1}{2}b + c$) so BE ($= \frac{1}{4}p$ i. e. $\frac{1}{4}b + \frac{1}{2}c$) to a fourth CF (which will be $= \frac{p^2}{8}$) 2. Make moreover as AB to AG (a to b) so

BH to GI (c to bc) and, as AB to AK (a to c) so BH to KL (c to cc) and the two quantities found GI and KL (bc and cc) being added into one sum will give the quantity $q = MN$, the half whereof MO will express the quantity $\frac{q}{2}$ in the

2 Rule,

Rule, and to be subtracted from the former $\frac{a}{2} + \frac{p^2}{8}$. Actually

therefore to determine the quantity AD not on the Ax, but on another Diameter of the described parabola n. 3. (because the quantity p is in the Equation) having made a perpendicular to the Ax $aE = p$ i.e. to the line BE n. 2. and from

4

E having drawn EA parallel to the ax, according to our form AD n. 1. transfer it only on the diameter of the parabola n. 3. from A to D, either by parts $\frac{a}{2}$ i.e. $\frac{1}{2}$ LM from A to c, and $\frac{bb}{8}$

i.e. $\frac{1}{8}$ CF n. 1. from c to D: But according to Baker's form, first you must put $\frac{a}{2} = \frac{1}{2}$ LM n. 1. from A to 1. Secondly you must put from 1 to 2 the quantity $\frac{p^2}{8} = CF$ n. 2.

Thirdly you must put from 2 to 3 backwards the quantity to be subtracted $\frac{q}{2} = MO$ n. 2. which being done, the point D

2

will be determined.

[It is evident by comparing these two ways of Construction, that we may join our forms not incommodiously to Baker's; because by ours the quantity AD was obtained more compendiously than by Baker's, which will also often happen hereafter. And where this Compendium cannot be had, there is another not inconsiderable one, that, if the quantities AD and DH determined according to both ways shall coincide, (which happens in the present case) we may be so much the more sure of the truth.]

2. As for DH by our form, you must put it from D to e on a perpendicular erected from D on the left hand, the quantity $b + 2c = BE$ n. 2. falling here upon the Ax. Then for the

4

quantity b^3 make n. 4. as a to $\frac{1}{2}bb$ (LM to LN) so $\frac{1}{8}b$ to $\frac{b^3}{16}$

(MO to NP) and this quantity must be put from e to f in a perpendicular to the Diam. Thirdly, for the quantity $\frac{bhc}{8}$

you

you must farther make $n. 4.$ as a to $\frac{1}{2}bb$ (DM to LN) so $\frac{1}{2}c$ to a fourth (MQ to NR) which must be put from f to g . Lastly the quantity $\frac{a^3}{2}$ (which is \equiv MO $n. 2.$) must be put

backwards (because to be subtracted) from g to H, which is the centre sought. In like manner by Baker's form, first $p \equiv BE$ is put from D to 1 even to the Ax. Secondly, for

the quantity $\frac{p^3}{16}$ make, $n. 4.$ as a to $\frac{p^2}{8}$ (LM to LS \equiv CF $n. 2.$) so $\frac{p}{2}$ to a fourth (MT \equiv AC $n. 2.$ to SV) and this

SV is further put ($n. 3.$) from 1 to 2. Thirdly, make in the same Fig. $n. 4.$ for the quantity $\frac{pq}{4}$, as a to $\frac{p}{2}$ (LM to MT) so $\frac{q}{2}$ to a fourth (LX to XZ) and this XZ is put back-

wads ($n. 3.$) from 2 to 3, which precisely coincides with the point g . Lastly the remaining quantity $\frac{r}{2}$ (\equiv MO $n. 2.$ and so by what we have said above, precisely coinciding with the interval $\frac{1}{2}gH$) is put backwards from g to H the Centre sought.

[Hence it appears again that Baker's form is more laborious than ours; tho' both accurately agree, and hereafter, for the most part, we shall use them both together, tho' in the work it self, rather in Figures, than in that tedious process of words, which we have here for once made use of, that it might be as an Example for the following Constructions.]

Having therefore found by one or both ways the Center H, and thence described a circle thro' the vertex of the parabola A, the intersection N will give the perpendicular to the diameter NO, the value of the quantity x sought.

PROBLEM IV.

TO divide a given angle NOP , or a given arch $NQTP$ (Fig. 51. n. 1.) into three equal parts; i. e. having given or assumed at pleasure the Radius NO , and consequently also the Chord of the arch NP , to find NQ the subtense of the third part of the given arch.

SOLUTION.

If NO be made unity, $NP = q$, and NQ be supposed $= z$; having drawn QS parallel to TO , you'll have three similar triangles NOQ , QNR and RQS . For since the angle QOP is double of the angle QON , and the same (as being at the Center) double also of the angle at the Periphery QNR ; it will be equal to the angle QON . But the angle at Q is common to both triangles: Therefore the whole are equi-angular, and consequently the legs NQ and NR equal, as also NO and QO ; and by the like reason also PY and PT . Wherefore if RS should be added to RY , the line NP by this addition would be triple of the line NQ ; and so would give the Equation, if RS was determined; which may be done by means of the $\triangle QRS$, similar to the two former NOQ and QNR ; for the angle RQS is equal to the alternate one $QOF = QNR$, and the angle at R common to the triangles QNR and RQS , &c. Wherefore

as NO to NQ so NQ to QR

$$1 \text{ --- } z \text{ --- } z \text{ --- } z^2$$

and as NQ to QR so QR to RS

$$z \text{ --- } z^2 \text{ --- } z^2 \text{ --- } \frac{z^4}{z}$$

z

Therefore according to what we have above said

$$q + z^3 = 3z; \text{ and subtracting } q$$

$$z^3 = 3z - q; \text{ or}$$

$$z^3 - 3z + q = 0$$

Therefore the Central Rule will be (supposing also unity NO for the *Latus Rectum*.)

Kk

$L \dagger$

$$\frac{L}{2} + \frac{q}{2} = AD \quad \text{i. e. by our form,} \quad \frac{1}{2} + \frac{3}{2} \quad \text{i. e. } 2NO = AD$$

$$\text{and } \frac{r}{2} = DH. \quad \text{and } \frac{q}{2} = DH.$$

Geometrical Construction. Having described your parabola (Fig. 51. n. 2.) take on its Ax (because the quantity p is wanting in the Equation) $AD = 2NO$, and from D having erected a perpendicular $= \frac{3}{2}NP$ to H ; that will be the Center, from which a circle described thro' A , by cutting the parabola in three places, will give the three roots of the Equation, viz. NO and no true ones, the first whereof will express the quantity sought NQ (n. 1.) the latter the line NV , being the subtense of the third part of the compl. of the arch; and MO will express the false root, which is equal to the former taken together: All the same as in *Cartes* p. 91. but here somewhat plainer and easier.

PROBLEM V.

HAVING three sides given of a quadrilateral Figure to be inscribed in a circle, AB , BC , CD , (Fig. 52. n. 1.) to find the fourth side, which shall be the Diameter of the Circle.

SOLUTION.

If we consider the business as already done, and make $AB = a$, $BC = b$, $CD = c$, and $AD = y$; we shall have first in the right-angled $\triangle ABD$, $\square BD = yy - aa$, and (since in the obtuse angled $\triangle BCD$ the $\square BD$ is $= \square BC + CD + 2 \square$ of BC into CE) if those two $\square BC + CD$ (i. e. $bb + cc$) be subtracted from $\square BD$ ($yy - aa$) you'll have 2. $yy - aa - bb - cc =$ to the two said rectangles of BC into CE . But these two rectangles may also be otherwise obtain'd, 3, if the segment CE be otherwise determined; which may be done by help of the similar $\triangle ABD$ and CED (for the angles at B and E are right ones, and ECD and BAD equal, because each with the same third BCD makes two right ones;

ones; the one ECD by reason of its contiguity, the other at A by the 22. *Euc. Lib. 3.*) viz. by inferring as DA to AB so DC to CE

$$y \text{ --- } a \text{ --- } c \text{ --- } \frac{ac}{y}$$

for now multiplying CE $\equiv \frac{ac}{y}$ by BC $\equiv b$, the \square of BC into CE will be $\equiv \frac{abc}{y}$ and two such $\frac{2abc}{y}$.

Now therefore $yy \text{ --- } aa \text{ --- } bb \text{ --- } cc \equiv \frac{2abc}{y}$; and multipl.

by y ,

$$\left. \begin{array}{l} y^3 * \text{ --- } aa \\ \text{ --- } bb \\ \text{ --- } cc \end{array} \right\} y = 2abc; \text{ i. e. by Baker's and Cartes's forms.}$$

$$\left. \begin{array}{l} y^3 * \text{ --- } aa \\ \text{ --- } bb \\ \text{ --- } cc \end{array} \right\} y \text{ --- } 2abc = 0.$$

Therefore the Central Rule will be (supposing the same quantity e. g. a for unity and *Lat. Rect.*)

$$\frac{L}{2} + \frac{q}{2} = AD \text{ and}$$

$$\frac{r}{2} = DH, \text{ i. e. according to our form,}$$

$$\frac{a}{2} + \frac{aa}{2} + \frac{bb}{2} + \frac{cc}{2} \text{ i. e. } \frac{a}{2} + \frac{bb}{2} + \frac{cc}{2} = AD, \text{ and}$$

Geometrical Construction, which, without any circumlocution, from our form is founded on the foll. in *Fig. 52. n. 2.*

$$LM = a \text{ n. 3. A 1.} = LM \text{ from n. 2.}$$

$$MN \text{ and } LP = b \text{ 1, 2} = \frac{1}{2} PQ$$

$$PQ = bb \text{ 2, 2} = \frac{1}{2} ST$$

$$LS \text{ and } MO = c \text{ DH} = PR$$

$$PR = bc \text{ MO and mo two false roots}$$

ST = cc NO the true root; upon which having described a semi-circle the quadrilateral will be easily made. According to *Baker's* form, for AD there would be *n. 3.* first

K k 2

A c

$Ac \equiv \frac{1}{2} LM$, then $cD \equiv \frac{q}{2} \equiv VX$, half the line VZ , which is compounded of LM , PQ and ST ; but DH is $\equiv PR$ as above.

PROBLEM VI.

HAVING given to form a right-angled Triangle the least side BA (Fig. 53. n. 1.) and the difference of the segments of the base, to find the difference of the sides, and so form the Triangle. If we represent the business as already done, having given AB and EC to find FC .

SOLUTION.

Make $AB \equiv a$, and $EC \equiv b$, and $FC \equiv x$; then will $BC \equiv a + x$: Therefore the $\square AC \equiv 2aa + 2ax + xx$ and the line $AC \sqrt{2aa + 2ax + xx}$ and $\sqrt{2aa + 2ax + xx} - b$. Now therefore ACE i. e. $\sqrt{2aa + 2ax + xx}$ multiplied by b or \sqrt{bb} i. e. $\sqrt{2aabb + 2abbx + bbxx}$ is $\equiv GCF$ [but GC is $\equiv 2a + x$] i. e. $2ax + xx$ by *Conf. 1. Prop. 47. Lib. 1. Mathes. E-nucl.* and squaring both sides

$$2aabb + 2abbx + bbxx \equiv 4aaxx + 4ax^3 + x^4;$$

and transposing all,

$$x^4 + 4ax^3 + 4aaxx - 2abbx - 2aabb \equiv 0.$$

$$\begin{matrix} (p) & (q) & (r) & (s) \\ \frac{L}{2} + \frac{p^2}{8} - \frac{q}{2} & \equiv & AD \end{matrix}$$

Therefore (taking a for 1 and the *Latus Rectum* of the parabola) the Central Rule will be,

$$\frac{L}{2} + \frac{p^2}{8} - \frac{q}{2} \equiv AD$$

$$\text{and } \frac{p}{4} + \frac{p^3}{16} - \frac{pq}{4} - \frac{r}{2} \equiv DH \text{ i. e. according to our form and}$$

Reduction,

$$\frac{a}{2} + \frac{16aa}{8} - \frac{4aa + bb}{2} \text{ i. e. } \frac{a + bb}{2} \equiv$$

Geometrical Construction. First from our form, the compendiousness whereof will here appear, for it requires only one preparation *n. 2.* in which $LM = a$, MN and $LO = b$, $OP = bb$, which being premis'd, and the diameter Ay (because the quantity p is in the Equation) being drawn (*n. 3.*) make $AI = \frac{1}{2} LM$, and $1, 2$ or $1 D = \frac{1}{2} OP$, and $DH = LM$. The rest therefore being also perform'd, which the quantity S occurring in the present Equation requires, according to the last precepts of our introduction, you'll have NO the value of x sought; whence (*n. 4.*) at the interval AB having describ'd a Circle, and made a right angle at B , if FC be made $=$ to the found NO , you'll have the $\triangle ABC$ required, and EC will be found at the beginning of the prescribed magnitude.

Now if you were to find the center H by *Baker's* form without our Reduction, 1. you must put of (*n. 3.*) $\frac{1}{2} AB$ from A to c . 2. For the quantity $\frac{p^2}{8}$ make as 1 to $\frac{p}{2}$ so $\frac{p}{2}$ to a fourth,

which would be $= 2AB$, viz. $2DM$, and to be set from c to d . 3. The quantity $\frac{q}{2}$ (to obtain which you must subtract

OP (*n. 2.*) from the quadruple of LM , and divide the remainder by 2) must be set off backwards from d to e , by thus determining the point D . 4. The quantity p , which here is precisely $= LM$, must be transferr'd from D to f on a perpendicular erected from D . 5. For the quantity $\frac{p^3}{16}$ make as 1

to $\frac{p^2}{8}$ ($= 2AB$) so $\frac{p}{2}$ (also $= 2AB$) to a fourth quadruple of $\frac{p}{2LM}$

LM ; and this must further be produc'd from f to the point g (which here the paper will not permit) 6. For the quantity $\frac{pq}{4}$ make as 1 to $\frac{p}{2}$ so $\frac{q}{2}$ to a fourth, (which would be $=$ to

the quadruple of LM , but taking away OP) which must be set backwards from g to b . 7. Lastly the quantity $\frac{r}{2}$ ($= OP$)

set off from b backwards or towards the right hand to i will at length give the point H required.

Another

Another Solution of the same Problem.

This Problem may be more easily solved, and will give a far more simple Equation, if you are to find not FD but AE. Make therefore (*n. 1. Fig. 53.*) $\square = x$, and the rest as above; AC will be $\square = x + b$, and its $\square = xx + 2bx + bb$; therefore the \square BC $\square = xx + 2bx + bb - aa$; therefore the \square of the tangent HC $\square = xx + 2bx + bb - 2aa$. But the rectangle ACE will be $bb + bx$. Therefore by *Prop. 47. Lib. 1. Math. E-nucl.*

$xx + 2bx + bb - 2aa = bb + bx$;
and turning all over to the right hand,

$$xx + bx - 2aa = 0; \text{ or}$$

$xx = -bx + 2aa$. Therefore by case 2 of affected quadratics,

$$x = -\frac{1}{2}b + \sqrt{\frac{1}{4}bb + 2aa}.$$

The *Geometrical Construction* may be performed according to the rules of quadratics *Fig. 54. n. 1.* as will be evident to any attentive Reader. Having therefore described a circle at the interval BA, whether it be done from any arbitrary center (see *n. 4. Fig. 53.*) or upon AE found in the *pref. Fig.* making an intersection at the said interval in B; and applying AE, and producing it until EC become equal to the given quantity *q*, and at length having drawn BC you'll have the triangle right-angled at B, and also the difference of the sides FC. But to make it more short and elegant; having determined AE by a little circle (*Fig. 54. n. 3.*) prolong it to the opposite part of the circumference in C, and draw AB and CB; for as the radius of the little circle is $\frac{1}{2}b$, so EC is $= b$.

Now if you would construct the Equation above by *Baker's* rule (that its universality may also be confirm'd by an Example in quadratics) *viz.*

$$x^2 + bx - 2aa = 0;$$

The central rule will be (taking *a* for 1 and the *L. R.*)

$$\frac{L + \frac{p^2 + q}{2}}{2} = AD$$

and

LVIII

and $\frac{p}{4} + \frac{p^3}{16} + \frac{pq}{4} = \text{DH. i. e. by our Reduction,}$

$$\frac{a}{2} + \frac{bb}{8} + \frac{aa}{4} \text{ i. e. } 1\frac{1}{2}a + \frac{bb}{8} = \text{AD}$$

$$\text{and } \frac{b}{4} + \frac{b^3}{16} + \frac{2aab}{4} \text{ i. e. } \frac{3b}{4} + \frac{b^3}{16} = \text{DH.}$$

The *Construction* therefore will consist in these: LM (n. 2. Fig. 54.) = a , MO = $\frac{1}{4}b$, LP = $\frac{1}{2}b$, therefore PR = $\frac{bb}{16}$

PN = PR viz. $\frac{bb}{8}$, therefore Q = $\frac{b^3}{16}$. In Fig. 53. n. 3.

E = $\frac{1}{4}b$, AI = $\frac{1}{2}$ LM, 1, 2, or 1D = PR; DI = LP, MO, 1, 2, or 1D = PQ. Having drawn a circle from thro' A you'll have the true root AD = to AE sought; and DD the false root.

NB. Hence it is evident that one Problem may have several Solutions and Constructions, some more easy and simple, others more compound and laborious; viz. according as the unknown quantity is assumed more or less commodious to the purpose: which may not be amiss here to note for the sake of Learners:

PROBLEM VII.

Suppose a right line BD (Fig. 55.) any how divided in A, to divide it again in C, so that the square of BA shall be to the square of AC as AC to CD.

SOLUTION.

Since the first segments BA and AD are given, call the first a and the other b , and call AC the quantity AC x ; and CD will be = $b - x$. Now therefore since we suppose as the \square of AB to the \square AC so AC to CD

$aa \quad \text{---} \quad xx \quad \text{---} \quad x \quad \text{---} \quad b - x$
 $aab \text{ --- } aax \text{ will } = x^3$, and transferring the quantities on the left hand to the right,
 $x^3 + aax \text{ --- } aab = 0$.

Where-

Wherefore the Central Rule (taking a for 1 and the $L. R.$) will be $\frac{1}{2} - \frac{q}{2} = AD$

and $\frac{r}{2} = DH$. i. e. by our form $\frac{a}{2} - \frac{aa}{2}$ i. e. $o = AD$, that

D may fall on the vertex of the parabola;

and $\frac{aab}{2}$ i. e. $\frac{b}{2} = DH$. The Construction therefore will

be very simple, as is evident from the fifty fifth Figure.

PROBLEM VIII.

THere is given AB the capital line of a horn work (which we represent (tho' rudely) n. 1. Fig. 56) and the Gorge AD , also part of the line of defence EF , to find the face BE , the flank DE , the curtain (or the chord) DF , also the angle of the Bastion ABE , &c. and so the whole delineation of the horn work. It is evident if you have the flank DE or the curtain DF , the rest will be had also. Suppose therefore, the capital line AB and the gorge AD , and part of the line of defence EF to be of the magnitudes denoted by the Letters a , b , c , on the right hand.

SOLUTION.

Make $AB = a$, $AD = b$, and $EF = c$, and $DF = x$; then will $AF = x + b$, and by reason of the similitude of the $\triangle \triangle BAF$ and EDE and ECB ,

as FA to AB so FD to DE

$$\frac{x+b}{a} = \frac{x}{\frac{ax}{x+b}}$$

But now $\square \square DF + DE$ are $= \square EF$ i. e. $\frac{aaxx}{xx+2bx+bb}$

$+ xx = cc$; or giving the same denomination to all the quantities on the left hand,

$$\frac{x^4 + 2bx^3 + aaxx + bb}{xx + 2bx + bb} = cc,$$

and

and multiplying both sides by $xx + 2bx + bb$;

$$x^4 + 2bx^3 + aaxx \equiv ccxx + 2bccx + bbcc;$$

$$+ bb$$

and translating all the quantities on the right hand by the contrary signs to the left,

$$x^4 + 2bx^3 + aaxx - 2bccx - bbcc \equiv 0.$$

$$+ bb$$

$$- cc$$

Wherefore (putting a for x and $L. Rectum$) the Central Rule will be,

$$\frac{L}{2} + \frac{p^2}{8} + \frac{q}{2} \text{ (because the quantity } q \text{ is negative in the E-}$$

quation, for cc is greater than $aa + bb$) $\equiv AD$;

and $\frac{p}{4} + \frac{p^3}{16} + \frac{pq}{4} - \frac{r}{2} \equiv DH$. or according to our Reduc-

tion,

$$\frac{a}{2} + \frac{bb}{2} + \frac{cc}{2} - \frac{aa}{2} - \frac{bb}{2} \text{ i. e. } \frac{cc}{2} \equiv AD$$

$$\text{and } \frac{2b}{4} + \frac{8b^3}{16} + \frac{2bcc}{4} - \frac{2aab}{4} - \frac{2b^3}{4} - \frac{2bc}{2}$$

$$\text{i. e. } \frac{b}{2} + \frac{b^3}{2} + \frac{bcc}{2} - \frac{aab}{2} - \frac{b^3}{2} - \frac{bcc}{2} \text{ i. e.}$$

$$\frac{0 - bcc}{2} \equiv DH.$$

Wherefore the *Geometrical Construction* requires no other preparatory determination by our form than of the quantities cc for AD , bcc for DH at the center, and $bbcc$ to determine

the radius of the circle; which are exhibited by *n. 2. Fig. 56.* viz. $NP \equiv cc$, $RS \equiv bcc$, $RV \equiv bbcc$, which are found by means of $LM \equiv a$, $LR \equiv b$, LN and $MO \equiv c$, $MQ \equiv NP$ and $MT \equiv RS$. Having therefore described a parabola, *n. 3.* and drawn its diameter, transfer $AD \equiv \frac{1}{2} NP$ upon it (because the quantity p is in the Equation) and also $\frac{1}{2} RS$ from D upon H perpendicularly, and on the right hand, (because $DH \equiv -\frac{1}{2} bcc$;) and so you'll have the center H ;

2

L 1

thro'

thro' which having drawn KAI so that AK shall be \equiv to the quantity $bbcc$ or S , i.e. RV, &c. a circle described at the interval HL will cut the parabola in M and N, and applying the magnitude NO it will be that of the Curtain sought; upon which, n. 4. having laid down the circumference of the horned work by help of the given lines AB and AD, you'll have the line EF, of the magnitude which was above supposed. Now if any one has a mind to do the same thing by Baker's way; by laying down first the interval AB $\equiv \frac{L}{2}$ and then making $bc \equiv \frac{p^2}{8}$, and lastly, putting cd for the

quantity $\frac{q}{2}$; he will fall upon the same point D, and in like

manner may express the other parts of the Central Rule by the intervals De, ef, fg , and setting back the last gb , he will fall upon the same center H: But this is done with a great deal more trouble and labour to determine so many quantities, and also is in more danger of erring by cutting off so many parts separately, as experience will shew; and thus we have by a new argument shewn the advantage of our Reduction.

Another Solution of the same Problem.

Things remaining as before (only assuming the given lines AB, AD and EF, n. 1. Fig. 56. one half less, that the Scheme may take up less room) make $BE \equiv x$, as the first or chief unknown quantity; then will $BF \equiv x + c$, and its $\square xx + 2cx + cc$: And since

as BE to $BC \equiv AD$ so BF to AF a fourth, which will be $\frac{x}{b} \equiv \frac{x+c}{x}$ and its square $\equiv \frac{bx + bc}{x}$ and its square $\equiv \frac{bbxx + 2bbcx + bbcc}{xx}$. Where

fore if this square be subtracted from the square of BF , there will remain the square of BA , i. e.

$$xx + 2cx + cc - \frac{bbxx + 2bbcx + bbcc}{xx} \equiv aa; \text{ i. e. all}$$

being reduced to the same denomination,

$$x^4 + 2cx^3 + ccxx - 2bbcx - bbcc \equiv aaxx; \\ -bb$$

or according to the forms of *Cartes* and *Baker*,

$$x^4 + 2cx^3 + ccxx - 2bbcx - bbcc = 0.$$

$$-aa$$

$$-bb$$

Therefore the Central Rule (putting again a for 1 and the L. R.) will be

$$\frac{L + p^2}{2 \quad 8} - \frac{q}{2} = AD$$

$$\text{and } \frac{p + p^3}{4 \quad 16} - \frac{pq}{4} - \frac{r}{2} = DH;$$

or by our Reduction,

$$\frac{a + cc}{2 \quad 2} - \frac{cc + aa + bb}{2} \text{ i. e. } a + \frac{bb}{2} = AD;$$

$$\text{and } \frac{c + c^3}{2 \quad 2} - \frac{c^3 + aac + bbc}{2} - \frac{bbc}{2} \text{ i. e. } c - \frac{bbc}{2} = DH.$$

Geometrical Construction. Having therefore described a parabola (*Fig* 56. n. 5.) and drawn the diameter Ay , make $AI = a$ and $1, 2 = \frac{bb}{2}$, so you'll have the point D ; make moreover D^3

or $2, 3 = c$, and backwards $3, 4 = \frac{bbc}{2}$ (we here omit to

express the Geometrical determination of these quantities $\frac{bb}{2}$

and $\frac{bbc}{2}$ as being very easy) and you'll have the point H , &c.

and there will come out the quantity sought NO ; which since it is equal to half BE n. 4. the business will be done; which *Baker's* form will also give, exactly the same, but after a more tedious process.

PROBLEM IX.

IN any Triangle ABC (the scheme whereof see n. 1. *Fig* 57.) suppose given the Perpendicular AD , and the differences of the least side from the two others EC and FC to find all the three sides.

L1 2

sides.

sides. i. e. Chiefly the least side AB which being found, the others will be so also.

SOLUTION.

Make $AD = a$, $EC = b$, and $FC = c$, $AB = x$; then will $BC = x + b$ and its square be $xx + 2bx + bb$, and $AC = x + c$ and its square be $xx + 2cx + cc$; and BD will be $\sqrt{xx - aa}$, and $DC = \sqrt{xx + 2cx + cc - aa}$. But the \square BC may also be obtain'd otherwise, and the Equation also, if \square $BD + DC + 2 \square$ of BD by DC be added into one sum according to *Prop. 4. Lib. 2. Eucl. viz.*

$$\begin{array}{r} 2xx + 2cx + cc - 2aa + \sqrt{4x^4 + 8cx^3 + 4cc} \} xx - \\ - 8aa \end{array}$$

$$8aacx + 4a^4 - 4aacc \text{ will be } = xx + 2bx + bb,$$

[For $DC = \sqrt{xx - aa + 2cx + cc}$, multiplied by $BD = \sqrt{xx - aa}$, gives the rectangle of the segments

$$\begin{array}{r} \sqrt{xx + 2cx + cc} \times \sqrt{xx - aa} = 2aacx + a^4 - aacc - 2aa \\ - 2aa \end{array}$$

and this doubled i. e. multiplied by $\sqrt{4}$, gives the quantity which is contain'd under the radical sign in the Equation]

Therefore turning all over on the left hand which are before the sign $\sqrt{\quad}$ to the right hand, prefixing to them the contrary signs, you'll have

$$\begin{array}{r} \sqrt{4x^4 + 8cx^3 + 4cc} \} xx - 8aacx + 4a^4 - 4aac \\ - 8aa \end{array}$$

$$= -xx + 2bx + bb - cc + 2aa, \text{ and taking away}$$

the *Vinculum* on the left hand, and squaring on the right

$$\begin{array}{r} 4x^4 + 8cx^3 + 4cc \} xx - 8aacx + 4a^4 - 4aacc \\ - 8aa \end{array}$$

$$\begin{array}{r} = x^4 + 4cx^3 - 4aa \} + 4b^3 \} + 4a^4 \\ - 4b \} + 2bb \} + 4c^3 \} + b^4 \\ + 6cc \} + 8aab \} + c^4 \\ - 8bc \} - 8aac \} + 4aabb \\ - 4bbc \} - 4aacc \\ - 4bcc \} - 2bbcc \end{array}$$

and

and adding and subtracting on both sides, as much as can be,

$$\begin{array}{rcl}
 3x^4 + 4cx^3 - 4aaxx & & \\
 = -b4x^3 + 2bb \left. \begin{array}{l} + 2cc \\ - 8bc \end{array} \right\} xx & \left. \begin{array}{l} + 4b^3 \\ + 4c^3 \\ + 8aab \\ - 4bbc \\ - 4bcc \end{array} \right\} x & \left. \begin{array}{l} + b^4 \\ + c^4 \\ + 4aabb \\ - 2bbcc \end{array} \right\}
 \end{array}$$

and transferring all to the left,

$$\begin{array}{rcl}
 3x^4 + 4b \left. \begin{array}{l} + 4c \end{array} \right\} x^3 & \left. \begin{array}{l} - 4aa \\ - 2bb \\ - 2cc \\ + 8bc \end{array} \right\} xx & \left. \begin{array}{l} - 4b^3 \\ - 4c^3 \\ - 8aab \\ + 4bbcc \\ + 4bcc \end{array} \right\} x & \left. \begin{array}{l} - b^4 \\ - c^4 \\ - 4aabb \\ + 2bbcc \end{array} \right\} = 0
 \end{array}$$

and dividing all by 3,

$$\begin{array}{rcl}
 x^4 + \frac{4}{3}b \left. \begin{array}{l} + \frac{4}{3}c \end{array} \right\} x^3 & \left. \begin{array}{l} - \frac{4}{3}aa \\ - \frac{2}{3}bb \\ - \frac{2}{3}cc \\ + \frac{8}{3}bc \end{array} \right\} xx & \left. \begin{array}{l} - \frac{4}{3}b^3 \\ - \frac{4}{3}c^3 \\ - \frac{8}{3}aab \\ + \frac{4}{3}bbcc \\ + \frac{4}{3}bcc \end{array} \right\} x & \left. \begin{array}{l} - \frac{1}{3}b^4 \\ - \frac{1}{3}c^4 \\ - \frac{4}{3}aabb \\ + \frac{2}{3}bbcc \end{array} \right\} = 0.
 \end{array}$$

Note, I sought this Equation also after two other ways;
 1 By a comparifon of the \square AC with the two fquares AB \dagger BC,
 after 2 \square CBD thence fubtracted, according to *Prop. 13. Lib 2. Eucl* which is the 46. *Li^h. 1. Math. Enucl.* and I form'd
 the fame with the prefent. 2. By putting at the beginning y
 for $x + b$ and z for $x + c$, and going on after the former meth-
 ods, 'till you have this Equation,

$$\begin{array}{rcl}
 x^4 - 2x^2 \left. \begin{array}{l} + 4aa \end{array} \right\} yy & \left. \begin{array}{l} - 2x^2 \\ - 2y^2 \end{array} \right\} zz & + y^4 + z^4 = 0.
 \end{array}$$

in which, when afterwards I fubftituted the values anfwering
 the quantities yy and zz , &c. This fame laft Equation came
 out a little eafier, but (NB) with all the contrary figns.

Now to form the Central Rule, and thence make the Geo-
 metrical Conftitution, we muft determine firft each of the
 quantities p , q , r and S , that we may know whether they
 are negative or pofitive; and you'll find (*n. 2. Fig. 57.*) $p =$
 $G2$ pofitive, $q = H^+$ negative, and $K^+ = S$ alfo negative;
 and that by help of the quantities $LM = b$ or 1 , MN and
 LO

LO $\equiv a$, OP $\equiv aa$, MQ and LR $\equiv c$, RS $\equiv ce$, and also LT $\equiv cc$, TV and LX $\equiv c^3$, XY $\equiv c^4$. Wherefore the form of the last Equation will be like this,

$x^4 + px^3 - qxx - rx - S \equiv 0$, and so the Central Rule (taking here b for 1 and the L. R.)

$$\frac{L}{2} + \frac{p^2}{8} + \frac{q}{2} \equiv AD$$

$$\text{and } \frac{p}{4} + \frac{p^3}{16} + \frac{pq}{4} - \frac{r}{2} \equiv DH.$$

Wherefore, having now described a parabola (as may be seen *n.* 4.) having found the diameter Ay transfer upon it first $Ab \equiv \frac{1}{2} LM$ (*n.* 2) and then $bc \equiv \frac{p^2}{8}$ (*n.* 3.) i. e. $\frac{p^2}{8}$; and

thirdly $cD \equiv \frac{q}{2}$ i. e. $\frac{1}{2} H^4$ (*n.* 2.) moreover from D to e put

off DB (*n.* 3. $\equiv \frac{p}{4}$, and from e to f put off $DR \equiv \frac{p^3}{16}$, and

from f to g put off $CF \equiv \frac{pq}{4}$; and from g backwards to b

put off half the quantity r , or 15 (*n.* 2.) and having done the rest as usual, you'll have NO, the side required of the Triangle to be described; the description whereof will be now easy (*n.* 5.) having all the three sides known. This may serve for an Examen, if having described a semi-circle AGB upon $AB \equiv NO$, you apply the given line AD, and from B thro' D draw indefinitely BDC: Then at the interval AB having described the Arches AE and BF, add the given line EC to BE, for thus having joined the points A and C, FC ought to be equal to FC before given.

SCHOLIUM.

WE have here omitted our Reduction, because it would be too tedious, and would express the quantities AD and DH (especially the latter) in terms too prolix. For AD would be $\equiv \frac{b}{2} + \frac{1}{2} bb + \frac{1}{2} cc - \frac{8}{9} bc + \frac{2}{3} da$ (*viz.* because $\frac{p^2}{8}$ is found

found $\equiv \frac{2}{3}bb + \frac{1}{3}bc + \frac{1}{3}cc$ and q taken in it self $\equiv \frac{2}{3}aa - \frac{1}{3}bb$

$\frac{1}{3}cc + 43cc$; but here [where by vertue of the Central Rule it is taken positively, when it is in it self negative] under contrary signs it is $\equiv \frac{2}{3}aa + \frac{1}{3}$ or $\frac{2}{3}bb + \frac{1}{3}$ or $\frac{2}{3}cc - \frac{1}{3}$ or $\frac{12}{9}bc$ or yet more contractedly (because b is unity) $AD \equiv \frac{1}{2}b + \frac{1}{9}b$ (i. e. $1\frac{1}{18}b$) $+ \frac{1}{9}cc - \frac{2}{9}c + \frac{2}{3}aa$; which parts may be expressed without any great difficulty on the Diameter Ay , by its portions $AI, 1, 2; 2, 3; 3D$: But the other quantity DH , or the definition of the Center H , would also have some tediousness, as because

p would be $\equiv b + c$

$$\frac{4}{p^3} \equiv \frac{4^{13} + 12bbc + 12bcc + 4c^3}{16}$$

$$\frac{16}{pq} \equiv \frac{6bcc + 6bbc - 4aab - 4aac - 2b^3 - 2c^3}{27}$$

$$\frac{4}{\text{or } 6bbc + 6bcc - 12aab - 6b^3 - 6c^3}$$

If you take away out of the quantities pq and r (since this latter is to be subtracted, and so left, as it is, under the sign $-$; but the other, also negative in it self, but here positively expressed in the Central Rule, must have all the contrary signs) I say, if you take out of these quantities those which destroy one another, and add the rest with the two former quantities, they will be $b + c$

$$- \frac{8aab + 4aac + 4bbc + 4bcc - 8b^3 - 8c^3}{9} \equiv DH.$$

or a little more contracted (because b is 1) $\frac{b + c}{27}$

$$- \frac{8aa + 4aac + 4c + 4cc - 8b^3 - 8c^3}{9} \equiv DH.$$

But now if any one has a mind to illustrate this by a numeral Example and try the truth, &c. of the quantities found; they may make e. g. $a \equiv 12$, $b \equiv 1$, and $c \equiv 2$; and they will

will easily find that in the last Equation the quantity p will be 4, and $q = 190$, $r = 388$, $S = 195$: Secondly in the Central Rule of *Baker* they'll find $\frac{L}{2} = \frac{1}{2}$, $\frac{p^2}{8} = 2$, and $\frac{q}{2} =$

95, and so the whole line $AD = 97\frac{1}{2}$; and further $\frac{p}{2} = 1$,

$\frac{p^3}{16} = 4$, $\frac{pq}{4} = 190$, and $\frac{r}{2} = 194$, and so the whole

line $DH = 195 - 194 = 1$. Thirdly, likewise in our Reduction (if we proceed by each part corresponding to *Baker's*) $\frac{b}{2} = \frac{1}{2}$, $\frac{1}{9}bb + \frac{1}{3}bc + \frac{1}{9}bc = 2$, and $\frac{1}{3}aa + \frac{1}{3}bb + \frac{1}{3}cc$

$= 4bc = 95$. The sum for $AD = 97\frac{1}{2}$; but further $\frac{b+c}{3} = 1$,

$$\frac{4b^3 + 12bbc + 12bcc + 4c^3}{3} = 4;$$

$$\frac{6bcc + 6bbc - 4aab - 2b^3 - 2c^3}{3} = 190;$$

and $\frac{2bbc + 2bcc - 4aab - 2b^3 - 2c^3}{3} = 194$ to be subtracted; and so the sum for $DH = 195 - 194 = 1$. Which same quantities will fourthly come out, if the quantities AD and DH contracted, as they are expressed in letters above, be resolved into numbers.

PROBLEM X.

YOU are to build a Fort on the given Polygons EAF (see Fig. 58. n. 1.) whose capital line AB shall equal the aggregate of the gorge and flank, and the squares of these added together shall be equal to the square of the given line GH , and the solid made by the multiplication of the square of the flank by the gorge, shall be equal to the cube of the given line IK .

SOLV.

LVIII

LIX

SOLUTION.

Make the Gorge $AC \equiv z$, whose square zz subtracted from bb the square of the given line b , will leave the square of the flank $DC \equiv bb - zz$. Now this square being multiplied by the gorge AC or z will give $bbz - z^3 \equiv g^3$, the cube of the given line IK ; and adding to both sides z^3 , and subtracting bbz , $0 \equiv z^3 - bbz + g^3$.

Therefore if we take g or IK for 1 and L^3 , g^3 will be the line g , and

The Central Rule : $\frac{L}{2} + \frac{g}{2} \equiv AD$.

$$\text{and } \frac{r}{2} \equiv DH.$$

i. e. according to our Reduction,

$$\frac{g}{2} + \frac{bb}{2} \equiv AD \text{ and } \frac{g}{2} \equiv DH.$$

Geometrical Construction. Having described a Parabola (*n.* 2. *Fig.* 58.) make on its ax $AI \equiv \frac{1}{2}IK$ and 1, 2, f. viz. 1D $\equiv \frac{1}{2}MN$ (from *n.* 1.) and $DH \equiv \frac{1}{2}IK$. Then having described a circle from H , and found the true root NO upon the given angle EAF (*n.* 3.) make $AC \equiv NO$, and having erected the perpendicular CD divide it by $AD \equiv GH$ (*n.* 1.) and make $AB \equiv AC + CD$; and the Fort will be drawn.

PROBLEM XI.

IN a right-angled Triangle ABC (which we denote by *n.* 1. *Fig.* 59.) having given the greater side AC , and made the less side $AB \equiv$ to the segment CE , which shall cut off from the base BC a perpendicular let fall from the right angle A ; to find these lines AB or CE , and consequently the whole triangle.

Mna

SOLU-

SOLUTION.

Make $AC = a$, CE or $AB = x$. Therefore, 1. you'll have $aa - xx = \square AE$. And because the $\triangle BEA$ and CAE are similar, you'll have as AC to CE so BA to AE

$$a \text{ --- } x \text{ --- } x \text{ --- } \frac{xx}{a}$$

And so, 2. $\square AE = \frac{x^4}{aa}$. Therefore

$$\frac{x^4}{aa} = aa - xx; \text{ and multipl. by } aa,$$

$x^4 = a^4 - aaxx$; or, according to the form of *Cartes* and *Baker*, transposing all to the left,

$$x^4 + aaxx - a^4 = 0 \text{ i. e.}$$

$$x^4 + qxx - S = 0.$$

Therefore (taking a for 1 and *L. R.*) the Central Rule will be $\frac{L}{2} - \frac{q}{2}$ i. e. $0 = AD$

and $\frac{r}{2}$ i. e. $0 = DH$; that H may fall on the vertex A .

Geometrical Construction. Since a is assumed for unity and L , the quantity S also and *Latus Rectum* i. e. AI and AK and consequently the mean proportional AL and the radius HL will be $=$ to the given side AC , and consequently at that interval having described a circle, thro' the Parabola rightly delineated, you'll have NO the value of the quantity x , i. e. of the lesser side AB . Having drawn therefore NA , which is $=$ to AC by Construction, if you draw to it the perpendicular AB cutting NO produc'd to B , you'll have the Triangle sought ABC , and AB (which will be a sign of a true Solution) will be found $= NO$ or CE .

Another Construction. Since in the Equation above found there is neither x^3 nor x , it may be look'd upon as a quadratick, and constructed after the same way, as several other like it among the Examples *n. 4.* viz. because $x^4 = -aaxx + a^4$; according to case 2 of affected quadraticks,

$$xx = \frac{aa + \sqrt{\frac{1}{4}a^4} + a^4}{\sqrt{\frac{1}{4}a^4}} \text{ i. e.}$$

$$\text{and } x = \sqrt{\frac{aa + \sqrt{\frac{1}{4}a^4}}{\frac{1}{4}a^4}} \text{ i. e. } \sqrt{\frac{aa}{\frac{1}{4}a^4} + \frac{\sqrt{\frac{1}{4}a^4}}{\frac{1}{4}a^4}}$$

Wherefore (*n. 3. Fig. 59.*) if AC be made $= a$ and $CD \frac{1}{4}a$, the mean proportional CG will be $= \sqrt{\frac{1}{4}a}$, and taking hence $GF = \frac{1}{2}a$, there will remain $FC = \sqrt{\frac{1}{4}a} - \frac{1}{2}a$: And now between this or CH equal to it, and unity AC, having found another mean proportional CE it will be the value of the quantity x sought $= NO$ (*n. 2.*)

PROBLEM XII.

IN a right-angled Triangle ABC (*Fig. 60. n. 1.*) there is given the Perpendicular BA, a segment of the Hypotenuse BD, and a segment of the Base EC, from C to the perpendicular DE let fall from the end of the segment BD; to find AE, DC, and consequently the Base AC and the Hypotenuse BC, and so the whole Triangle.

SOLUTION.

Make $AB = a$, $BD = b$, and $EC = c$, and $DC = x$; which being given, the rest cannot be wanting: Therefore $xx - cc = \square DE$. But the same $\square DE$ may be had, if you infer

$$\begin{array}{l} \text{as BC to BA so DC to DE} \\ b \div x = a = x = \frac{ax}{b \div x} \end{array}$$

And then square the quantity DE, the square will be

$$\frac{aaxx}{xx + 2bx + bb} = xx - cc;$$

and multiplying both sides by $xx + 2bx + bb$,

$$aaxx = x^4 + 2bx^3 + bbxx - 2bccx - bbcc;$$

and subtracting also $aaxx$,

$$\begin{array}{r} x^4 + 2bx + bbxx - 2bccx - bbcc = 0. \\ -aa \\ -cc \end{array}$$

M m 2

Which

C ————— D
 B ————— G

V. X Y Z

Pag. 89.

LXI

so PV = to it, that PX may be $\frac{p^3}{16}$; and lastly Py = $\frac{1}{2}q$, that

PZ may be $\frac{pq}{4}$. These being thus prepar'd, if (n. 4) Ab be

made = $\frac{1}{2}$ AB (n. 1.) bc = RT, and cd backwards = $\frac{1}{2}$ PD we shall light on the point D; and, if we make De = $\frac{1}{2}$ BD, ef = PX (n. 5. which interval was too big to be represented in the Paper) and from f you put backwards fg = PZ, and on from g beyond to the right hand gh = 2RS; we shall light on the point H, &c. Which of these two methods is the shortest and fittest for practice, any one, never so little experienc'd, may here see; and first Learners may take notice if they would construct by Baker's form, in the Diagrams n. 3. n. 5: and the like, they must take care to make the angles ~~PLP~~, SPT pretty large; which we have here represented the less to save charges in cutting on Copper.

PROBLEM XIII.

Having given the Diameter of a Circle CD (n. 1. Fig. 61.) and the line BG, which falls on it perpendicularly, (which we have here only rudely delineated) to find the point A, from which a right line AC being drawn shall so cut the line BG in F, that AF, FG, CD shall be three continual Proportionals.

SOLUTION.

If CF be found, the point A will be also had, and the section of the line BG will be made. Make therefore CF = x , and (because the perpendicular BG is given, there will also be given the segments of the diameter CG and GD) make GD = b , and CG = c ; then will BG = \sqrt{bc} and CD = $b + c$. Since therefore the $\triangle CAD$ and $\triangle CGF$ are right-angled, and have the angle at C common, they will be similar.

Therefore, as CF to CG so CD to CA

$$x \text{ --- } c \text{ --- } b+c \text{ --- } \frac{bc+c}{x}$$

There-

Therefore $AF = \frac{bc + cc}{x} - x$, and $FG \sqrt{xx - cc}$.

But by the Hypothesis,

as AF to FG so FG to GD

$$\frac{bc + cc - xx}{x} = \sqrt{xx - cc} = \sqrt{xx} - cc - b.$$

Therefore the rectangle of the extremes will be equal to that of the means,

$$\frac{bbc + bcc - bxx}{x} = xx - cc;$$

and multiplying by x ,

$$bbc + bcc - bxx = x^3 - ccx;$$

and transposing all to the left,

$x^3 + bxx - ccx - bbc - bcc = 0$; i. e. by the Cartesian form,

$$x^3 + pxx - qx - r = 0.$$

Therefore (taking b for 1 and L .) the Central Rule will be,

$$\frac{L}{2} + \frac{p^2}{8} + \frac{q}{2} = AD$$

and $\frac{p}{4} + \frac{p^3}{16} + \frac{pq}{4} - \frac{r}{2} = DH.$

or according to our Reduction,

$$\frac{b}{2} + \frac{bb}{8} + \frac{cc}{2} \text{ i. e. } \frac{5b}{8} + \frac{cc}{2} = AD$$

and $\frac{b}{4} + \frac{b^3}{16} + \frac{cc}{4} - \frac{c - cc}{2} \text{ i. e. } \frac{5b}{16} - \frac{cc}{4} - \frac{c}{2} = DH.$

Geometrical Construction. Having described upon the given line CD (n. 2.) a semi circle, and apply'd in it the given perpendicular BG , as the figure shews, you'll have the segments of the Diameter $GD = b$, and to the quantity p in *Baker's* form, and $CG = c$, which (n. 3. where $LM = b$, LO and $MN = c$) will give $OP = cc$ and to the quantity q . Wherefore having describ'd a Parabola (n. 4.) and the line $VZ = 2\frac{1}{2}b$, having cut off the fourth part of XZ , and the eighth of YZ (whereof the one will be $= 2\frac{1}{2}b$, viz. $\frac{5b}{8}$ and

the

the other to $\frac{5b}{8}$ if you transfer $AI \equiv XZ$ upon the diame-

ter of the Parabola Ay , and moreover $1, 2$ or $1D \equiv$ to half OP (*n. 3.*) and transversely $D^3 \equiv YZ$ and backwards $3, 4 \equiv \frac{1}{4}OP$, as also $4, 5 \equiv \frac{1}{2}CG$ (*n. 2.*) you'll have the center H , and having describ'd a Circle at the interval HA , the root NO must be transferr'd from (*n. 2.*) C to F , and continued to A the point sought. In *Baker's* Form (because the quantity p is $\equiv b$ or 1) $\frac{p^2}{8}$ is $\equiv \frac{b}{8}$ and $\frac{b^3}{16} \equiv \frac{b}{16}$, and the quantity q or cc

$\equiv OP$, (*n. 3.*) make therefore in the Diameter of the Parabola $Ab \equiv \frac{1}{2}GD$, and $bc \equiv \frac{1}{8}GD$, (*n. 2.*) and lastly $cd \equiv \frac{1}{4}OP$ (*n. 3.*) and you'll have the point D the same as before. Make moreover $De \equiv \frac{1}{4}GD$ and $cf \equiv \frac{1}{16}CG$, and then backwards $fg \equiv \frac{1}{4}OP$, and lastly $gb \equiv \frac{1}{2}GD$, and you'll have the same center H , and the coincidence of the parts in both forms will be pleasant to observe; which otherwise seldom happens.

Other Solutions of the same Problem.

Carolus Renaldinus, from whose *Treatise de Resol. & Compos. Math. Lib. 2.* we have the present Problem, proceeds to solve it in another way, changing it plainly into another Problem: *viz.* he observes, 1. That the angles FAD (see *n. 1.* of our *61. Fig.*) and FGD , since both are right ones on the same common base FD , are in circle. Hence he infers, 2. (by vertue of the *Coroll.* of the *26. Prop. 3. Eucl.*) that the $\square DCG$ and ACF are equal, and consequently CD, CA, FC and CG are four continued proportionals. Then he observes, 3. That GD is the excess of the first of these proportionals above the fourth CG , and AF is the excess of the second AC above the third CF ; and so, since 4. the rectangle of AF and GD is \equiv to the square of the mean proportional FG (for AF, FG, GD , are supposed to be continual proportionals) and this $\square FG$ is the excess, by which the square of the third CF exceeds the square of the fourth CG ; now the present Problem will be 5. reduc'd to this other: Having two right-lines (CD and CG) given to find two such mean proportionals (AC and FC) that the \square of the excess of the first above the fourth (*viz.* of FA into GD) shall be equal to the excess, by

by which the square of the third (FC) exceeds the square of the fourth (CG) viz. by the square FG.

Wherefore instead of the former he solves this latter Problem, putting for CG, b , for GD, c , so that the first of the given lines CD shall be $\equiv b + c$, and the other GD $\equiv b$; calling the first mean proportional AC, x ; and thence denominating the latter $\frac{bb + bc}{x}$ (viz. multiplying the fourth by

the first, and dividing the product by the second) and moreover he finds the excess of the first ($b + c$) above the fourth (b) to be c , and the excess of the second (x) above the third ($\frac{bb + bc}{x}$) to be $x - \frac{bb + bc}{x}$ i. e. $\frac{xx - bb - bc}{x}$; so that the

\square of these two excesses is $\frac{c}{x} \times \frac{xx - bb - bc}{x} = \frac{c}{x} \frac{xx - bb - bc}{x}$, and because

the \square of the third FC is $\equiv \frac{b^4 + 2b^3c + bbcc}{x}$, having subtra-

cted $bb \equiv \square$ GC, there is given the \square FG $\equiv \frac{b^4 + 2b^3c + bbcc}{x} - bb$

$\equiv \frac{b^4 + 2b^3c + bbcc - b^2x}{x}$ of the excesses we just now found. So that now you'll have the Equation

$$\frac{b^4 + 2b^3c + bbcc - b^2x}{xx} = \frac{c}{x} \frac{xx - bb - bc}{x}, \&c.$$

We also endeavour'd to find another Solution, by finding an Equation from the line BD (*n. 1. Fig. 61.*) as which might be twice obtain'd by means of the two right-angled Triangles FAD and FGD, since it is the hypotenusa of both. But here, besides the former denominations of our Solution we must first give a denomination to the line AD, by making as CF to FG so CD to AD

$$x - \sqrt{xx - cc} = b + c \text{ so } a - a\sqrt{xx - cc}, \&c.$$

But whosoever shall prosecute this Solution of ours, or that of Renaldinus to the end, will find much more labour and difficulty in either, than in the first we have given.

APPENDIX.

THE Invention of the special Central Rule for the case of *Problem 1. Of Cubick Equations, &c.* which may serve for an Example for all the other special ones which belong to our Synopsis, p. 354. (and from these special ones) to find a general one.

In *Fig. 47. n. 4.* make $AD \equiv b$, $DH \equiv d$; and so we shall have the \square of the radius $HA \equiv bb + dd$. But this \square HA or HN , may be also had otherwise, by putting,

2. For the quantity NO , as sought, the letter x , and by inferring from the known Property of the Parabola, as L to NO so NO to AO

$$\frac{NO}{L} = \frac{AO}{NO} \Rightarrow NO^2 = AO \cdot L$$

and subtracting $AD \equiv b$ from AO , you'll have DO or $PN \equiv \frac{xx}{L} - b$; whose \square is $\frac{x^4}{L^2} - \frac{2bxx}{L} + bb$.

But you also have $PH \equiv DH - DP$ or NO , *i. e.* $d - x$; whose \square is therefore $\equiv dd - 2dx + xx$.

Wherefore adding the \square PN and PH , you'll have the \square $HN \equiv \frac{x^4}{L^2} - \frac{2bxx}{L} + xx - 2dx + dd + bb$.

Wherefore the Equation will now be readily had:

$$\left(\square HN \right) = \left(\square HA \right) \Rightarrow \frac{x^4}{L^2} - \frac{2bxx}{L} + xx - 2dx + dd + bb = bb + dd;$$

and taking from both sides $bb + dd$,

$$\frac{x^4}{L^2} - \frac{2bxx}{L} + xx - 2dx = 0.$$

and multiplying all by L^2

and also dividing by x ,

$$x^3 - 2bLx - 2L^2d = 0.$$

3. And now farther comparing this Equation with a form like ours in *Probl. 1. viz.* with this,

$$x^3 * * \text{---} r \equiv 0 ;$$

It is manifest, since in ours also the third term, *viz.* q is wanting, that the correspondent one to it in the former $\text{---} 2bL$ \dagger L^2 is equivalent to 0; and adding to both sides $2bL$, L^2 will be made $\equiv 2bL$; and dividing by $2L$, $\frac{L^2}{2L}$ will $\equiv b$ or

AD. In like manner, since $\text{---} r$ in our form answers to the quantity $2L^2d$ in the former; $2L^2d$ will $\equiv r$, and, dividing by $2L^2$, DH or d will $\equiv \frac{r}{2L^2}$: Which is the other Mem-

ber of the Central Rule to be found.

NB. The Analytick Art has this particularly to be admired in in, that it finds its own Rules by an Analysis : Whereof we have here an evident Example, and several others in the Resolution of affected Quadratics, *p.* 345. and the following.

II.

The Invention of the Central Rule, in the Case of Fig. 11. and the like.

1. $\square HA \equiv bb \dagger dd$ as above.

2. Putting x for NO, as sought, we may infer from a new Property of the Parabola, which we have demonstrated *Prop. 6. lib. 2*

as L to NO so OR to AO, *i. e.* (putting a for BA or FO given; that NO --- OF *i. e.* NF or OR shall be $\equiv x \text{---} a$)

as L to x so $x \text{---} a$ to $\frac{xx \text{---} ax}{L} \equiv AO$.

Therefore having subtracted AD *i. e.* b from AO, you'll have DO or HP $\equiv \frac{xx \text{---} ax \text{---} b}{L}$; whose \square is

$x^4 \text{---}$

Specious Analysis.

$$\frac{x^4 - 2ax^3 + ax^2}{L} - \frac{2bxx + 2abx + bb}{L}$$

But PN also is \square NO — PO or HD, \square $x^2 - 2dx + dd$.

Therefore having added the \square PH and PN, there will come out \square HN

$$\frac{x^4 - 2ax^3 + ax^2}{L^2} - \frac{2bxx + 2abx + xx - 2dx + bb + dd}{L}$$

\square HA i. i. $bb + dd$; and taking away from both sides $bb + dd$,

$$\frac{x^4 - 2ax^3 + ax^2}{L^2} - \frac{2bxx + 2abx + xx - 2dx}{L} = 0;$$

and multiplying every where by L^2 and diving by x ,

$$x^3 - 2ax^2 + aax - 2Lbx + 2Lab + 2L^2x - 2L^2d = 0.$$

3. And now comparing this Equation with another form, which shall be like an Equation arising from the Solution of some Problem, e. g. with this $x^3 - pxx + qx - r = 0$; to this you'll have \square this other,

$$\left. \begin{array}{l} x^3 - 2axx + aa \\ - 2Lb \\ + L^2 \end{array} \right\} x + \frac{2Lab}{-2L^2d}.$$

4. Wherefore, because in these equal forms, first, $2a$ is $\square p$, a will be $\square \frac{p}{2}$ i. e. the line BA. Secondly, Because aa (or p^2)

$$+ L^2 - 2Lb = q;$$

Therefore $2Lb = \frac{p^2}{2} + L^2 - q$, and dividing by $2L$,

$$b = \frac{L^2}{2L} \text{ (or } \frac{L}{2}) + \frac{p^2 - q}{8L} = AD.$$

Thirdly, Because $2abL - 2dL^2 = r$ i. e.

$2abL - r = 2dL^2$; therefore dividing by $2L^2$, d will be $\square \frac{2abL - r}{2L^2}$ i. e.

$d = \frac{ab}{L} - r$ i. e. resolving $\frac{ab}{L}$ into equivalent Terms expressed by p and q ,

$d = \frac{p}{4} + \frac{p^3}{16L^2} - \frac{pq}{4L^2} - \frac{r}{2L^2}$; which is the other member of the Central Rule to be found.

$$\text{viz. } a \text{ is } \frac{p}{2}; b = \frac{L}{2} + \frac{p^2}{8L} - \frac{q}{2L}$$

$$\text{Therefore } ab \text{ will be } \frac{Lp}{4} + \frac{p^3}{16L} - \frac{pq}{4L}$$

$$\text{Therefore } \frac{ab}{L} = \frac{p}{4} + \frac{p^3}{16L^2} - \frac{pq}{4L^2}$$
